7 Detailed Description

7.1 Overview

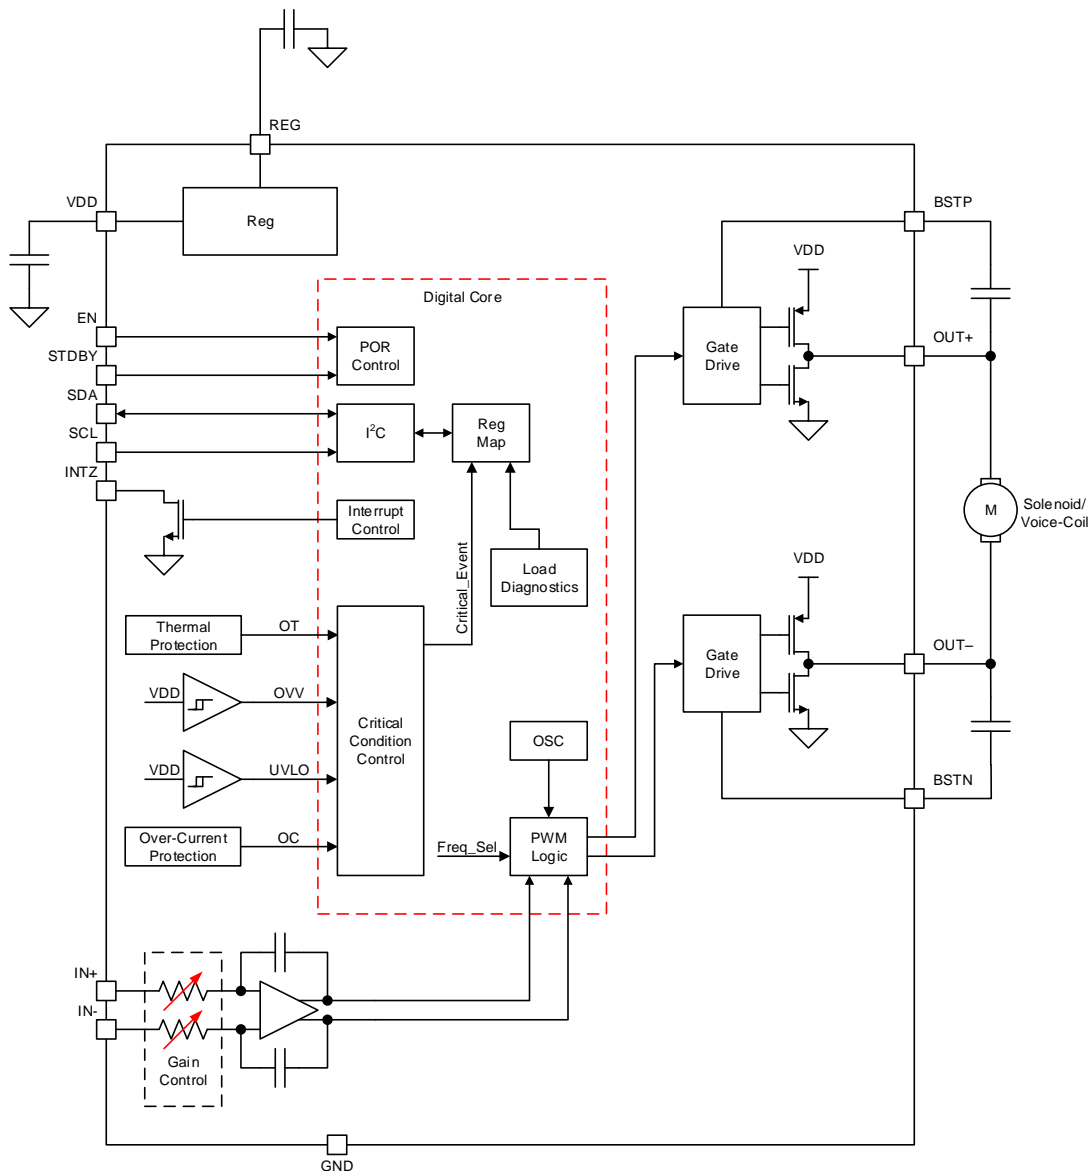

The DRV2510-Q1 device is a high current haptic driver specifically designed for inductive loads, such as solenoids and voice coils.

The output stage consists of a full H-bridge capable of delivering 3 A of peak current.

The design uses an ultra-efficient switching output technology developed by Texas Instruments, but with features added for the automotive industry. The DRV2510-Q1 device provides protection functions such as undervoltage lockout, over-current protection and over-temperature protection. This technology allows for reduced power consumption, reduced heat, and reduced peak currents in the electrical system.

The DRV2510-Q1 device is automotive qualified. The integrated load-dump protection reduces external voltage clamp cost and size, and the onboard load diagnostics report the status of the actuator through the digital interface.

7.2 Functional Block Diagram

7.3 Feature Description

7.3.1 Analog Input and Configurable Pre-amplifier

The DRV2510-Q1 device features a differential input stage that cancels common-mode noise that appears on the inputs. The DRV2510-Q1 device also features four gain settings that are configurable via I²C. Please see the Programming Sections for register locations.

表 1. Gain Configuration Table

GAIN	INPUT IMPEDANCE
20 dB	60 kΩ
26 dB	30 kΩ
32 dB	15 kΩ
36 dB	9 kΩ

7.3.2 Pulse-Width Modulator (PWM)

The DRV2510-Q1 device features BD modulation scheme with high bandwidth, low noise, low distortion, and excellent stability.

The BD modulation scheme allows for smaller ripple currents through the load. Each output switches from 0 V to the supply voltage. With no input, the OUT+ and OUT- pins are in phase with each other so that there is little or no current in the load. For positive differential inputs, the duty cycle of OUT+ is greater than 50% and the duty cycle of OUT- is lower than 50% for a positive differential output voltage. The opposite is true for negative differential inputs. The voltage across the load sits at 0 V throughout most of the switching period, reducing the switching current, which reduces the I²R losses in the load.

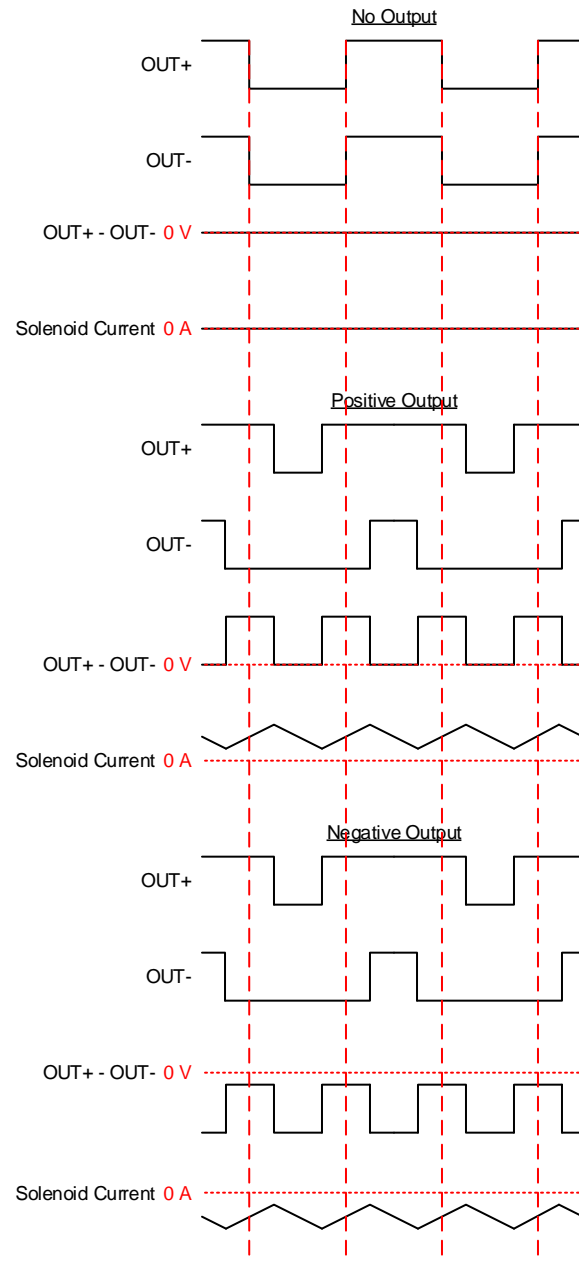

图 5. BD Mode Modulation

7.3.3 Designed for low EMI

The DRV2510-Q1 device design has minimal parasitic inductances due to the short leads on the package. This dramatically reduces EMI that results from current passing from the die to the system PCB. The design incorporates circuitry that optimizes output transitions that causes EMI. Follow the recommended design requirements in the [Design Requirements](#) section.

7.3.4 Device Protection Systems

The DRV2510-Q1 device features a complete set of protection circuits carefully designed to protect the device against permanent failures due to shorts, over-temperature, over-voltage, and under-voltage scenarios. The INTZ pin signals if an error is detected.

Additionally, the DRV2510-Q1 device is not damaged by adjacent pin to pin shorts.

Under-voltage	VDD < 4 V	pulled low	output in high impedance. I ² reset.
Over-voltage	VDD > 21 V	pulled low	output in high impedance. I ² updated.

7.3.4.1 Diagnostics

The device incorporates load diagnostic circuitry designed for detecting and determining the status of output connections. The device supports the following diagnostics:

- Short to GND
- Short to VDD
- Short across load
- Open load

The device reports the presence of any of the short or open conditions to the system via I²C register read.

1. **Load Diagnostics**—The load diagnostic function runs on de-assertion of EN or when the device is in a fault state (dc detect, overcurrent, overvoltage, undervoltage, and overtemperature). During this test, the outputs are in a Hi-Z state. The device determines whether the output is a short to GND, short to VDD, open load, or shorted load. The load diagnostic biases the output, which therefore requires limiting the capacitance value for proper functioning. The load diagnostic test takes approximately 229 ms to run. Note that the *check* phase repeats up to five times if a fault is present or a large capacitor to GND is present on the output. On detection of an open load, the output still operates. On detection of any other fault condition, the output goes into a Hi-Z state, and the device checks the load continuously until removal of the fault condition. After detection of a normal output condition, the output starts. The load diagnostics run after every other overvoltage (OV) event. The load diagnostic for open load only has I²C reporting. All other faults have I²C and INTZ pin assertion.

The device performs load diagnostic tests as shown in 图 6.

图 7 illustrates how the diagnostics determine the load based on output conditions.

图 6. Load Diagnostics Sequence of Events

图 7. Load Diagnostic Reporting Thresholds

2. **Faults During Load Diagnostics**—If the device detects a fault (overtemperature, overvoltage, undervoltage) during the load diagnostics test, the device exits the load diagnostics, which may result in a small transient on the output.

7.4 Device Functional Modes

The DRV2510-Q1 device has multiple power states to optimize power consumption.

7.4.1 Operation in Shutdown Mode

The NRST pin of the DRV2510-Q1 device puts the device in a shutdown mode. When NRST is asserted (logic low), all internal blocks of the device are off to achieve ultra low power. I²C is not operational in this mode and the output is in Hi-Z state.

7.4.2 Operation in Standby Mode

The STDBY pin of the DRV2510-Q1 device puts the device in a standby mode. When STDBY is asserted (logic high), some internal blocks of the device are off to achieve low power while preserving the ability to wake up quickly to achieve low latency waveform playback.

7.4.3 Operation in Active Mode

The DRV2510-Q1 device is in active mode when it has a valid supply, and it is not in either shutdown or standby modes. In this mode the DRV2510-Q1 device is fully on and reproducing at the output the input times the gain.

7.5 Programming

7.5.1 General I²C Operation

The I²C bus employs two signals, SDA (data) and SCL (clock), to communicate between integrated circuits in a system. The bus transfers data serially, one bit at a time. The 8-bit address and data bytes are transferred with the most-significant bit (MSB) first. In addition, each byte transferred on the bus is acknowledged by the receiving device with an acknowledge bit. Each transfer operation begins with the master device driving a start condition on the bus and ends with the master device driving a stop condition on the bus. The bus uses transitions on the data pin (SDA) while the clock is at logic high to indicate start and stop conditions. A high-to-low transition on the SDA signal indicates a start, and a low-to-high transition indicates a stop. Normal data-bit transitions must occur within the low time of the clock period. 图 8 shows a typical sequence. The master device generates the 7-bit

Programming (接下页)

slave address and the read-write (R/W) bit to start communication with a slave device. The master device then waits for an acknowledge condition. The slave device holds the SDA signal low during the acknowledge clock period to indicate acknowledgment. When the acknowledgment occurs, the master transmits the next byte of the sequence. Each device is addressed by a unique 7-bit slave address plus a R/W bit (1 byte). All compatible devices share the same signals through a bidirectional bus using a wired-AND connection.

The number of bytes that can be transmitted between start and stop conditions is not limited. When the last word transfers, the master generates a stop condition to release the bus. 图 8 shows a generic data-transfer sequence.

Use external pull-up resistors for the SDA and SCL signals to set the logic-high level for the bus. Pull-up resistors between 660 Ω and 4.7 k Ω are recommended. Do not allow the SDA and SCL voltages to exceed the DRV2510-Q1 supply voltage, V_{DD} .

注

The DRV2510-Q1 slave address is 0x6C (7-bit), or 1101100 in binary.

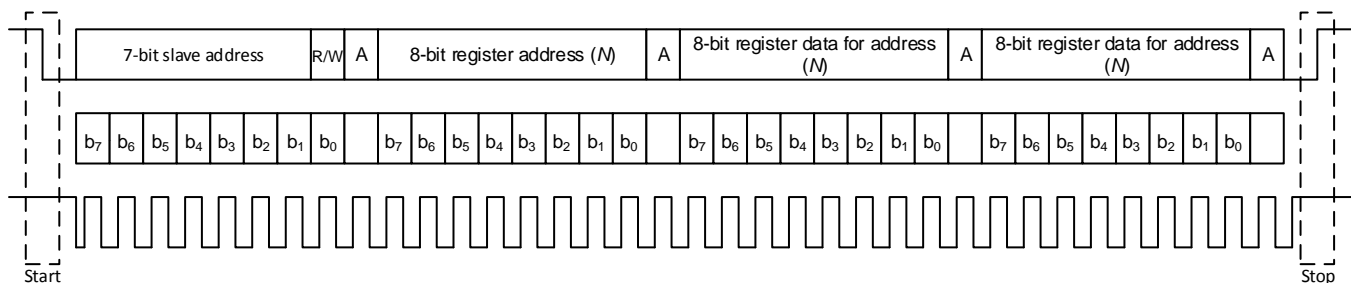

图 8. Typical I²C Sequence

The DRV2510-Q1 device operates as an I²C-slave 1.8-V logic thresholds, but can operate up to the V_{DD} voltage. The device address is 0x5A (7-bit), or 1011010 in binary which is equivalent to 0xB4 (8-bit) for writing and 0xB5 (8-bit) for reading.

7.5.2 Single-Byte and Multiple-Byte Transfers

The serial control interface supports both single-byte and multiple-byte R/W operations for all registers.

During multiple-byte read operations, the DRV2510-Q1 device responds with data one byte at a time and begins at the signed register. The device responds as long as the master device continues to respond with acknowledges.

The DRV2510-Q1 supports sequential I²C addressing. For write transactions, a sequential I²C write transaction has taken place if a register is issued followed by data for that register as well as the remaining registers that follow. For I²C sequential-write transactions, the register issued then serves as the starting point and the amount of data transmitted subsequently before a stop or start is transmitted determines how many registers are written.

7.5.3 Single-Byte Write

As shown in 图 9, a single-byte data-write transfer begins with the master device transmitting a start condition followed by the I²C device address and the read-write bit. The read-write bit determines the direction of the data transfer. For a write-data transfer, the read-write bit must be set to 0. After receiving the correct I²C device address and the read-write bit, the DRV2510-Q1 responds with an acknowledge bit. Next, the master transmits the register byte corresponding to the DRV2510-Q1 internal-memory address that is accessed. After receiving the register byte, the device responds again with an acknowledge bit. Finally, the master device transmits a stop condition to complete the single-byte data-write transfer.

Programming (接下页)

图 9. Single-Byte Write Transfer

7.5.4 Multiple-Byte Write and Incremental Multiple-Byte Write

A multiple-byte data write transfer is identical to a single-byte data write transfer except that multiple data bytes are transmitted by the master device to the DRV2510-Q1 device as shown in 图 10. After receiving each data byte, the DRV2510-Q1 device responds with an acknowledge bit.

图 10. Multiple-Byte Write Transfer

7.5.5 Single-Byte Read

图 11 shows that a single-byte data-read transfer begins with the master device transmitting a start condition followed by the I²C device address and the read-write bit. For the data-read transfer, both a write followed by a read actually occur. Initially, a write occurs to transfer the address byte of the internal memory address to be read. As a result, the read-write bit is set to 0.

After receiving the DRV2510-Q1 address and the read-write bit, the DRV2510-Q1 device responds with an acknowledge bit. The master then sends the internal memory address byte, after which the device issues an acknowledge bit. The master device transmits another start condition followed by the DRV2510-Q1 address and the read-write bit again. On this occasion, the read-write bit is set to 1, indicating a read transfer. Next, the DRV2510-Q1 device transmits the data byte from the memory address that is read. After receiving the data byte, the master device transmits a not-acknowledge followed by a stop condition to complete the single-byte data read transfer. See the note in the [General I²C Operation](#) section.

图 11. Single-Byte Read Transfer

7.5.6 Multiple-Byte Read

A multiple-byte data-read transfer is identical to a single-byte data-read transfer except that multiple data bytes are transmitted by the DRV2510-Q1 device to the master device as shown in 图 12. With the exception of the last data byte, the master device responds with an acknowledge bit after receiving each data byte.

8 Application and Implementation

注

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

8.1 Application Information

The DRV2510-Q1 device is a high-efficiency driver for inductive loads, such as solenoids and voice-coils. The typical use of the device is on haptic applications where short, strong waveforms are desired to create a haptic event that will be coming from the application processor.

8.2 Typical Applications

8.2.1 Single-Ended Source

To use the DRV2510-Q1 with a single-ended source, apply either a voltage divider to bias INB to 3 V, tie to GND or use a 0.1- μ F cap from INB to GND to have the device self bias. Apply the single-ended signal to the INA pin.

8.2.1.2 Detailed Design Procedure
8.2.1.2.1 Optional Components

Note that in the diagrams, there are a few optional external components. These optional external components may be needed in the application to meet EMI/EMC standards and specifications by filters necessary frequency spectrums.

8.2.1.2.2 Capacitor Selection

A bulk bypass capacitor should be mounted between VBAT and GND. The capacitance needs to be >22 uF with a X5R or better rating on the power pins to GND. Also include two ceramic capacitors in the ranges of 220 pF to 1 uF and 100 nF to 1 uF. The bootstrap capacitors, BSTA and BSTB, should be 220-nF ceramic capacitors of quality X5R or better rated for at least the maximum rating of the pin.

8.2.1.2.3 Solenoid Selection

The DRV2510-Q1 solenoid driver can accommodate a variety of solenoids. Solenoids should have an equivalent resistance of 1.6 Ω or greater. Solenoids with lower resistances are prone to driving high currents. A maximum peak current of 3-A should not be exceeded.

8.2.1.2.4 Output Filter Considerations

The output filter is optional and is mainly for limiting peak currents. A second-order Butterworth low-pass filter with the cut-off frequency set to a few kilohertz should be sufficient. See [公式 2](#), [公式 3](#), and [公式 4](#) for example filter design.

$$H(s) = \frac{1}{s^2 + \sqrt{2}s + 1} \quad (1)$$

$$L_x = \frac{\sqrt{2} \times R_L}{2\omega_0} \quad (2)$$

$$2 \times C_F = \frac{\sqrt{2}}{2 \times \frac{R_L}{2} \times \omega_0} \quad (3)$$

$$\omega_0 = 2\pi \times f \quad (4)$$

8.2.1.3 Application Curves

These application curves were taken using an HA200 solenoid with a 100-g mass, and the acceleration was measured using the DRV-AAC16-EVM accelerometer. The following scales apply to the graphs:

- Output Differential Voltage scale is shown on the plots at 5-V/div
- Acceleration scale is 5.85-G/div
- Current scale is 2-A/div

图 20. Voltage and Acceleration vs Time (Ramp Wave)

图 21. Voltage and Acceleration vs Time (1/2 Sine Wave)

8.2.1.4 Differential Input Diagram

To use the DRV2510-Q1 with a differential input source, apply both inputs differentially from a control source (GPIO, DAC, etc...).

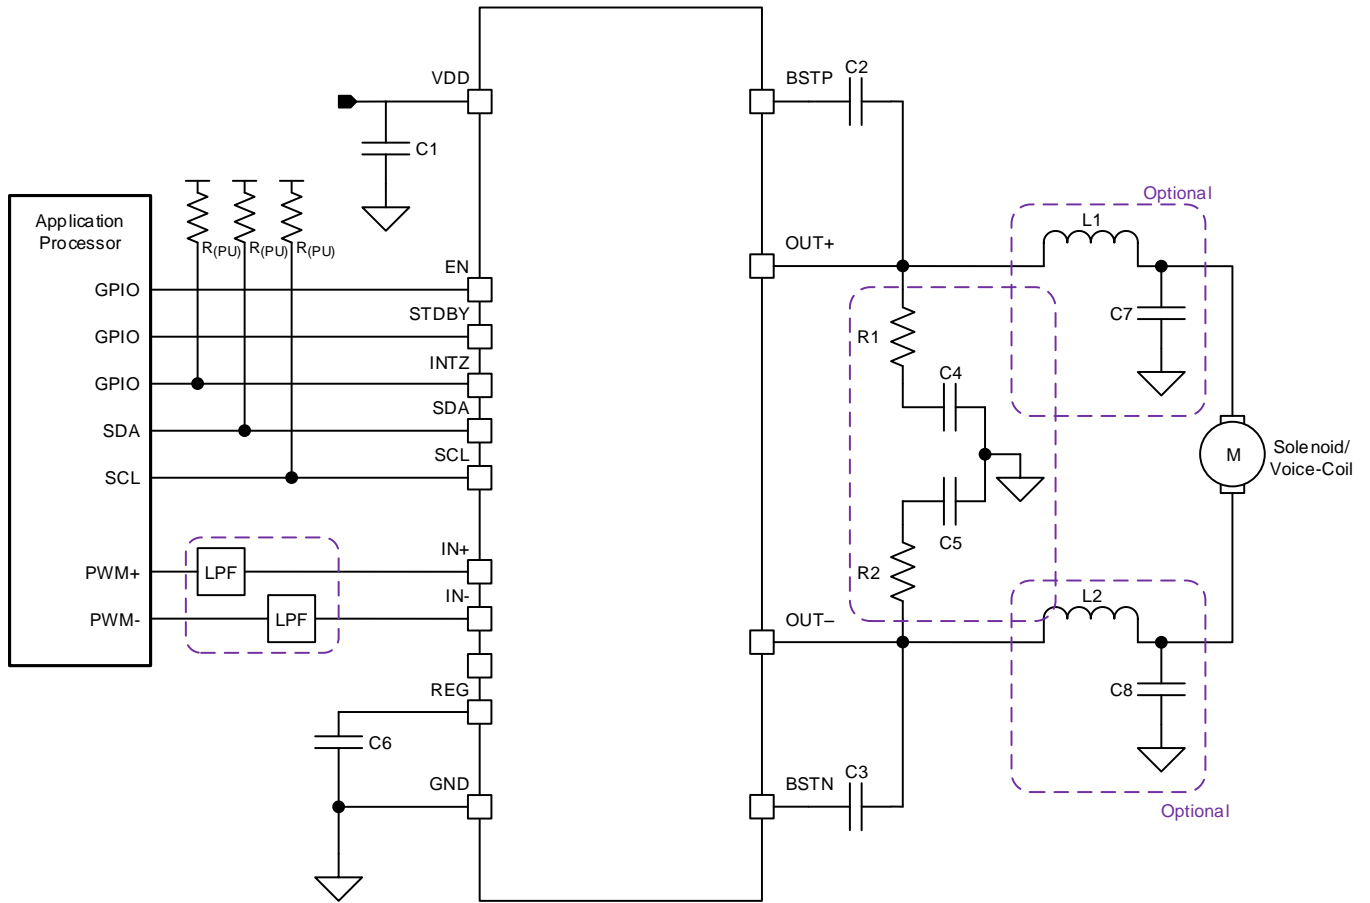

图 22. Typical Application Schematic

9 Power Supply Recommendations

The DRV2510-Q1 device operates from 5 V - 18 V and this supply should be able to handle high surge currents in order to meet the high current draws for haptics effects. Additionally the DRV2510-Q1 should have 22- μ F, 10- μ F and 0.1- μ F ceramic capacitors near the VDD pin for additional decoupling from trace routing.

10 Layout

10.1 Layout Guidelines

The EVM layout optimizes for thermal dissipation and EMC performance. The DRV2510-Q1 device has a thermal pad down, and good thermal conduction and dissipation require adequate copper area. Layout also affects EMC performance. It is best practice to use the same/similar layout as shown below in the DRV2510Q1EVM.

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

TBD: The Pb-Free/Green conversion plan has not been defined.

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.
