

ADSxx54 双路高速 16 位、14 位和 12 位 同步采样模数转换器

1 特性

- 16 位、14 位和 12 位引脚兼容系列
- 双通道同步采样
- 支持全差分输入
- 高速：
 - ADS8354: 16 位, 700kSPS
 - ADS7854: 14 位, 1MSPS
 - ADS7254: 12 位, 1MSPS
- 出色的直流性能：
 - ADS8354:
 - 16 位丢码率 (NMC) 差分非线性 (DNL), ± 2.5 最低有效位 (LSB), 最大积分非线性 (INL)
 - ADS7854:
 - 14 位 NMC DNL, ± 1.5 LSB, 最大 INL
 - ADS7254:
 - 12 位 NMC DNL, ± 1 LSB, 最大 INL
- 出色的交流性能：
 - ADS8354:
 - 93dB 信噪比 (SNR), -100dB 总谐波失真 (THD)
 - ADS7854:
 - 88dB SNR, -95dB THD
 - ADS7254:
 - 72dB SNR, -90dB THD
- 双路、可编程和经缓冲的 2.5V 内部基准电压
- 在 -40°C 至 125°C 的扩展工业温度范围内完全额定运行
- 小封装尺寸：
16 引脚超薄型四方扁平无引线 (WQFN) 封装

(3mm x 3mm) 和 16 引脚薄型小外形尺寸 (TSSOP) 封装

2 应用

- 电机控制：
使用编码器进行位置测量
- 光纤网络：掺铒光纤放大器 (EDFA) 增益控制环路
- 保护中继器
- 电源质量测量
- 三相电源控制
- 可编程逻辑控制器

3 说明

ADS8354、ADS7854 和 ADS7254 均属于引脚兼容的双路高速同步采样模数转换器 (ADC) 产品系列, 支持全差分模拟输入。

每个器件均包含两个可独立编程的基准电压源, 可用于系统级的增益校准。并且配有一个可在宽电源供电范围内运行的灵活串行接口, 从而轻松实现与多种主机控制器的通信。该系列器件支持两种低功耗模式, 可针对给定输出优化功耗。所有器件都在扩展工业温度范围 (-40°C 至 $+125^{\circ}\text{C}$) 内完全额定运行, 并且采用引脚兼容的 WQFN-16 (3mm x 3mm) 和 TSSOP-16 封装。

器件信息⁽¹⁾

部件号	封装	封装尺寸 (标称值)
ADSxx54	TSSOP (16)	5.00mm x 4.40mm
	WQFN (16)	3.00mm x 3.00mm

(1) 如需了解所有可用封装, 请见数据表末尾的可订购产品附录。

ADS7253	12	Single-ended and pseudo-differential	12	±1	73.5 (typ)

6 Pin Configurations and Functions

Pin Functions

NAME	PIN NO.		I/O	DESCRIPTION
	TSSOP	WQFN		
AINM_A	2	16	Analog input	Negative analog input, channel A
AINM_B	7	5	Analog input	Negative analog input, channel B
AINP_A	1	15	Analog input	Positive analog input, channel A
AINP_B	8	6	Analog input	Positive analog input, channel B
AVDD	16	14	Supply	Supply voltage for ADC operation
$\overline{\text{CS}}$	11	9	Digital input	Chip-select signal; active low
DVDD	9	7	Digital I/O supply	Digital I/O supply
GND	15	13	Supply	Digital ground
REFGND_A	4	2	Supply	Reference ground potential A
REFGND_B	5	3	Supply	Reference ground potential B
REFIO_A	3	1	Analog input/output	Reference voltage input/output, channel A
REFIO_B	6	4	Analog input/output	Reference voltage input/output, channel B
SCLK	12	10	Digital input	Clock for serial communication
SDI	10	8	Digital input	Data input for serial communication
SDO_A	13	11	Digital output	Data output for serial communication, channel A and channel B
SDO_B	14	12	Digital output	Data output for serial communication, channel B
Thermal pad	—	Thermal pad	Supply	Exposed thermal pad (only for WQFN). TI recommends connecting this pin to the printed circuit board (PCB) ground.

7 Specifications

7.1 Absolute Maximum Ratings⁽¹⁾

over operating free-air temperature range (unless otherwise noted)

	MIN	MAX	UNIT
AVDD to REFGND_x or DVDD to GND	-0.3	6	V
Analog (AINP_x and AINM_x) and reference input (REFIO_x) voltage with respect to REFGND_x	REFGND_x - 0.3	AVDD + 0.3	V
Digital input voltage with respect to GND	GND - 0.3	DVDD + 0.3	V
Ground voltage difference REFGND_x-GND		0.3	V
Input current to any pin except supply pins		±10	mA
Maximum virtual junction temperature, T _J		150	°C

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

7.2 Handling Ratings

		MIN	MAX	UNIT	
T _{stg}	Storage temperature range	-65	150	°C	
V _(ESD)	Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001, all pins ⁽¹⁾	-2000	2000	V
		Charged device model (CDM), per JEDEC specification JESD22-C101, all pins ⁽²⁾	-500	500	

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
 (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

7.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	NOM	MAX	UNIT
AVDD	Analog supply voltage		5		V
DVDD	Digital supply voltage		3.3		V

7.4 Thermal Information

THERMAL METRIC ⁽¹⁾		ADS8354, ADS7854, ADS7254		UNIT
		RTE (WQFN)	PW (TSSOP)	
		16 PINS	16 PINS	
R _{θJA}	Junction-to-ambient thermal resistance	33.3	86.9	°C/W
R _{θJC(top)}	Junction-to-case (top) thermal resistance	29.5	21	
R _{θJB}	Junction-to-board thermal resistance	7.3	39.1	
ψ _{JT}	Junction-to-top characterization parameter	0.2	0.8	
ψ _{JB}	Junction-to-board characterization parameter	7.4	38.4	
R _{θJC(bot)}	Junction-to-case (bottom) thermal resistance	0.9	N/A	

- (1) For more information about traditional and new thermal metrics, see the *IC Package Thermal Metrics* application report, [SPRA953](#).

7.5 Electrical Characteristics: ADS8354

All minimum and maximum specifications are at $T_A = -40^{\circ}\text{C}$ to 125°C , $AVDD = 5\text{ V}$, $DVDD = 3.3\text{ V}$, $V_{REF_A} = V_{REF_B} = V_{REF} = 2.5\text{ V}$ (internal), and $f_{DATA} = 700\text{ kSPS}$, unless otherwise noted.

Typical values are at $T_A = 25^{\circ}\text{C}$, $AVDD = 5\text{ V}$, and $DVDD = 3.3\text{ V}$.

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
RESOLUTION						
Resolution			16			Bits
DC ACCURACY⁽¹⁾						
NMC	No missing codes	32-clock mode	16			Bits
INL	Integral nonlinearity	32-clock mode	-2.5	±1	2.5	LSB
DNL	Differential nonlinearity	32-clock mode	-0.99	±0.7	2	LSB
E_{IO}	Input offset error		-1	±0.5	1	mV
	E_{IO} match	ADC_A to ADC_B	-1	±0.5	1	mV
dE_{IO}/dT	Input offset thermal drift			±1		μV/°C
E_G	Gain error	Referenced to the voltage at REFIO_x	-0.1	±0.05	0.1	%FS
	E_G match	ADC_A to ADC_B	-0.1	±0.05	0.1	%FS
dE_G/dT	Gain error thermal drift	Referenced to the voltage at REFIO_x		±1		ppm/°C
CMRR	Common-mode rejection ratio	Both ADCs, dc to 20 kHz		70		dB
AC ACCURACY⁽²⁾						
SINAD	Signal-to-noise + distortion	$V_{REF} = 2.5\text{ V}$, ± V_{REF} input range, 32-clock mode		88.6		dB
		$V_{REF} = 2.5\text{ V}$, ±2 × V_{REF} input range, 32-clock mode		88.4		dB
		$V_{REF} = 5\text{ V}$ (external), ± V_{REF} input range, 32-clock mode		92.2		dB
SNR	Signal-to-noise ratio	$V_{REF} = 2.5\text{ V}$, ± V_{REF} input range, 32-clock mode		89		dB
		$V_{REF} = 2.5\text{ V}$, ±2 × V_{REF} input range, 32-clock mode		89		dB
		$V_{REF} = 5\text{ V}$ (external), ± V_{REF} input range, 32-clock mode		93		dB
THD	Total harmonic distortion	$V_{REF} = 2.5\text{ V}$, ± V_{REF} input range, 32-clock mode		-99		dB
		$V_{REF} = 2.5\text{ V}$, ±2 × V_{REF} input range, 32-clock mode		-97.5		dB
		$V_{REF} = 5\text{ V}$ (external), ± V_{REF} input range, 32-clock mode		-100		dB
SFDR	Spurious-free dynamic range	$V_{REF} = 2.5\text{ V}$, ± V_{REF} input range, 32-clock mode		100		dB
		$V_{REF} = 2.5\text{ V}$, ±2 × V_{REF} input range, 32-clock mode		99		dB
		$V_{REF} = 5\text{ V}$ (external), ± V_{REF} input range, 32-clock mode		100		dB
ISOXT	ADC-to-ADC isolation	$f_{IN} = 15\text{ kHz}$ at 10 %FS, $f_{NOISE} = 25\text{ kHz}$ at FS		-110		dB

(1) LSB = least significant bit.

(2) All ac parameters are tested at -0.5 dBFS and a 20-kHz input frequency.

7.6 Electrical Characteristics: ADS7854

All minimum and maximum specifications are at $T_A = -40^\circ\text{C}$ to 125°C , $AVDD = 5\text{ V}$, $DVDD = 3.3\text{ V}$, $V_{REF_A} = V_{REF_B} = V_{REF} = 2.5\text{ V}$ (internal), and $f_{DATA} = 1\text{ MSPS}$, unless otherwise noted.

Typical values are at $T_A = 25^\circ\text{C}$, $AVDD = 5\text{ V}$, and $DVDD = 3.3\text{ V}$.

8 Detailed Description

8.1 Overview

These devices belong to a family of pin-compatible, dual, high-speed, simultaneous-sampling, analog-to-digital converters (ADCs). The ADS8354, ADS7854, and ADS7254 support fully-differential input signals. The devices provide a simple, serial interface to the host controller and operate over a wide range of analog and digital power supplies.

These devices have two independently programmable internal references to achieve system-level gain error correction. The [Functional Block Diagram](#) section provides a functional block diagram of the device.

8.2 Functional Block Diagram

8.3 Feature Description

8.3.1 Reference

The device has two simultaneous sampling ADCs (ADC_A and ADC_B). ADC_A and ADC_B operate with reference voltages V_{REF_A} and V_{REF_B} present on the REFIO_A and REFIO_B pins, respectively. The REFIO_A and REFIO_B pins should be decoupled with the REFGND_A and REFGND_B pins, respectively, with 10- μ F decoupling capacitors.

The device supports operation either with an internal or external reference source, as shown in [Figure 84](#). The reference voltage source is determined by setting bit 6 of the configuration register (CFR.B6). Note that this bit is common to ADC_A and ADC_B.

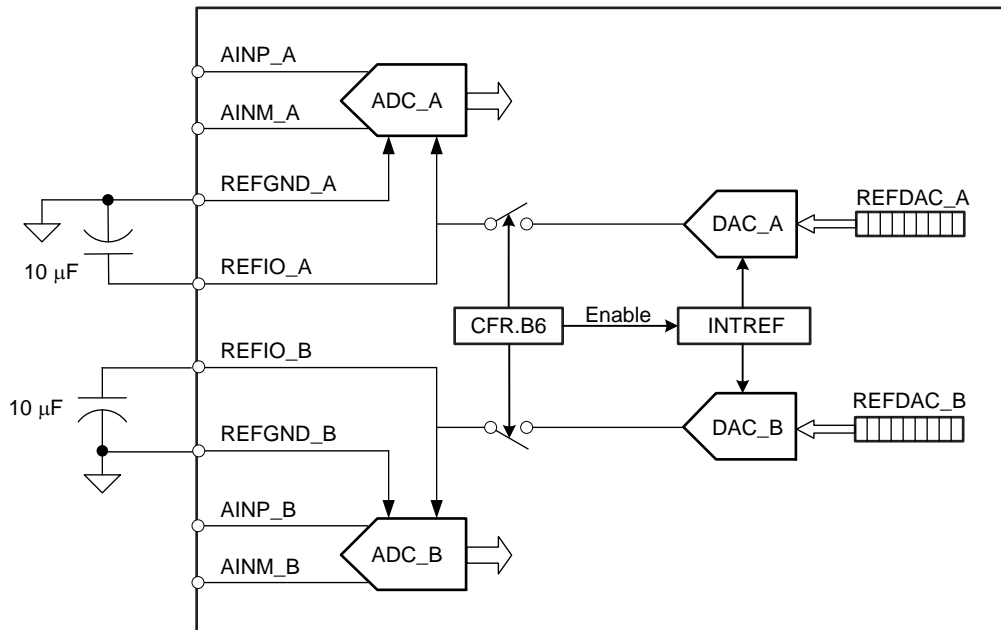

Figure 84. Reference Configurations and Connections

When CFR.B6 is 0, the device shuts down the internal reference source (INTREF) and ADC_A and ADC_B operate on external reference voltages provided by the user on the REFIO_A and REFIO_B pins, respectively.

When CFR.B6 is 1, the device operates with the internal reference source (INTREF) connected to REFIO_A and REFIO_B via DAC_A and DAC_B, respectively. In this configuration, V_{REF_A} and V_{REF_B} can be changed independently by writing to the respective user-programmable registers, REFDAC_A and REFDAC_B, respectively. Refer to the [REFDAC Registers \(REFDAC_A and REFDAC_B\)](#) section for more details.

Feature Description (continued)

8.3.2 Analog Inputs

The ADS8354, ADS7854, and ADS7254 support fully-differential analog input signals on both ADC channels. These inputs are sampled and converted simultaneously by the two ADCs, ADC_A and ADC_B. ADC_A samples and converts ($V_{AINP_A} - V_{AINM_A}$), and ADC_B samples and converts ($V_{AINP_B} - V_{AINM_B}$).

Figure 85a and Figure 85b show equivalent circuits for the ADC_A and ADC_B analog input pins, respectively. Series resistance, R_S , represents the on-state sampling switch resistance (typically 50 Ω) and C_{SAMPLE} is the device sampling capacitor (typically 40 pF).

Figure 85. Equivalent Circuit for the Analog Input Pins

8.3.2.1 Analog Input: Full-Scale Range Selection

The full-scale range (FSR) supported at the analog inputs of the device is programmable with bit B9 of the configuration register (CFR.B9). This bit is common for both ADCs (ADC_A and ADC_B). The FSR is given by Equation 1 and Equation 2 :

$$\text{For CFR.B9} = 0, \text{FSR_ADC_A} = \pm V_{REF_A} \text{ and } \text{FSR_ADC_B} = \pm V_{REF_B} \quad (1)$$

$$\text{For CFR.B9} = 1, \text{FSR_ADC_A} = \pm 2 \times V_{REF_A} \text{ and } \text{FSR_ADC_B} = \pm 2 \times V_{REF_B}$$

where:

- V_{REF_A} and V_{REF_B} are the reference voltages going to ADC_A and ADC_B, respectively (as described in the Reference section). (2)

Therefore, with appropriate settings of the REFDAC_A and REFDAC_B registers and CFR.B9, the maximum dynamic range of the ADC can be used.

Note that while using CFR.B9 set to 1, care must be taken so that the ADC analog supply (AVDD) is as in Equation 3 and Equation 4:

$$2 \times V_{REF_A} \leq AVDD \leq AVDD(\text{max}) \quad (3)$$

$$2 \times V_{REF_B} \leq AVDD \leq AVDD(\text{max}) \quad (4)$$

Feature Description (continued)
8.3.2.2 Analog Input: Common-Mode Voltage Range

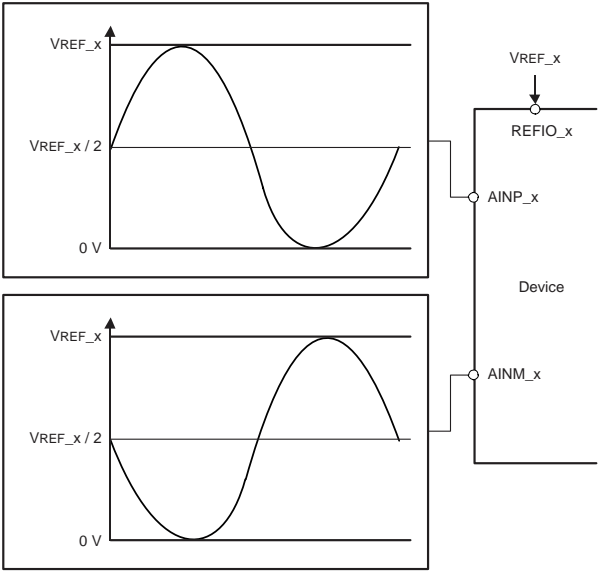

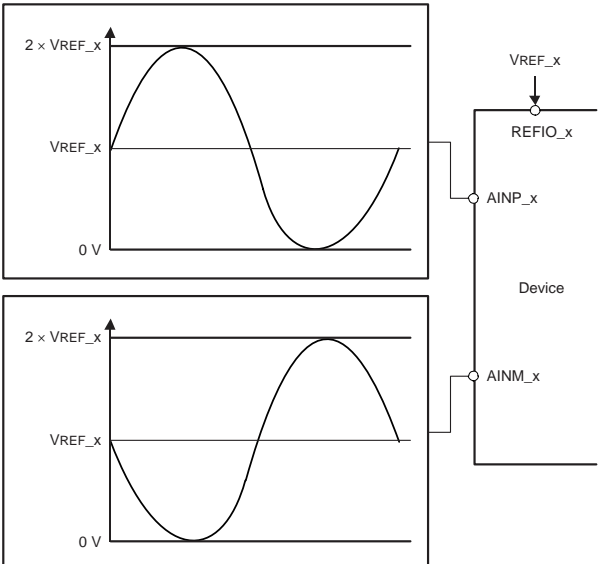

The ADS8354, ADS7854, and ADS7254 support fully-differential input signals. Equation 5 and Equation 6 provide the common-mode voltage for the ADC_A and ADC_B differential inputs.

$$V_{CM,A} = FSR_ADC_A / 2 \quad (5)$$

$$V_{CM,B} = FSR_ADC_B / 2 \quad (6)$$

The various input configurations supported by the device are shown in Table 1.

Table 1. Input Configurations

INPUT RANGE SELECTION	INPUT COMMON-MODE RANGE	CONNECTION DIAGRAM
CFR.B9 = 0 (FSR_ADC_A = ±V _{REF_A}) (FSR_ADC_B = ±V _{REF_B})	$V_{CM,A} = \left[\frac{V_{REF,A}}{2} \right] \pm 0.1 \text{ V}$ $V_{CM,B} = \left[\frac{V_{REF,B}}{2} \right] \pm 0.1 \text{ V}$	
CFR.B9 = 1 (FSR_ADC_A = ±2 × V _{REF_A}) (FSR_ADC_B = ±2 × V _{REF_B})	$V_{CM,A} = V_{REF,A} \pm 0.1 \text{ V}$ $V_{CM,B} = V_{REF,B} \pm 0.1 \text{ V}$	

8.3.3 Transfer Function

The device output is in twos complement format. Device resolution for a fully-differential input is calculated by Equation 7:

$$1 \text{ LSB} = (2 \times \text{FSR_ADC_x}) / (2^N)$$

where:

- N = 16 (ADS8354), 14 (ADS7854), or 12 (ADS7254)
- FSR_ADC_x is the full-scale input range of the ADC (refer to the *Analog Input* section for more details) (7)

Table 2 shows the different input voltages and the corresponding output codes from the device.

Table 2. Transfer Characteristics

INPUT VOLTAGE (AINP_x – AINM_x), ±V _{REF_x} RANGE	INPUT VOLTAGE (AINP_x – AINM_x), ±2 × V _{REF_x} RANGE	INPUT VOLTAGE	OUTPUT CODE (Hex)			
			CODE	ADS8354	ADS7854	ADS7254
< -V _{REF_x}	< -2 × V _{REF_x}	NFSC	NFSC	8000	2000	800
-V _{REF_x} + 1 LSB	-2 × V _{REF_x} + 1 LSB	NFSR	NFSC + 1	8001	2001	801
-1 LSB	-1 LSB	-1 LSB	MC	FFFF	3FFF	FFF
0	0	0	PLC	0000	0000	000
> V _{REF_x} - 1 LSB	> 2 × V _{REF_x} - 1 LSB	PFSR - 1 LSB	PFSC	7FFF	1FFF	7FF

Figure 86 shows the ideal transfer characteristics for the device.

Figure 86. Ideal Transfer Characteristics for a Fully-Differential Analog Input

8.4 Device Functional Modes

The device provides three user-programmable registers: the configuration register (CFR), the REFDAC_A register, and the REFDAC_B register. These registers support write (refer to the [Write to User Programmable Registers](#) section) and readback (refer to the [Reading User-Programmable Registers](#) section) operations and allow the user to customize ADC behavior for specific application requirements.

The device supports four interface modes (refer to the [Conversion Data Read](#) section), two low-power modes (refer to the [Low-Power Modes](#) section), and short-cycling/reconversion feature (refer to the [Frame Abort, Reconversion, or Short-Cycling](#) section).

8.5 Register Maps and Serial Interface

8.5.1 Serial Interface

The device uses the serial clock (SCLK) for synchronizing data transfers in and out of the device.

The $\overline{\text{CS}}$ signal defines one conversion and serial transfer frame. A frame starts with a $\overline{\text{CS}}$ falling edge and ends with a $\overline{\text{CS}}$ rising edge. Between the start and end of the frame, a minimum of N SCLK falling edges must be provided to validate the read or write operation. As shown in [Table 3](#), N depends upon the interface mode used to read the conversion result. When N SCLK falling edges are provided, the write operation attempted in the frame is validated and the internal user-programmable registers are updated on the subsequent $\overline{\text{CS}}$ rising edge. This $\overline{\text{CS}}$ rising edge also ends the frame.

Table 3. SCLK Falling Edges for a Valid Write Operation

INTERFACE MODE	MINIMUM SCLK FALLING EDGES REQUIRED TO VALIDATE WRITE OPERATION N
32-CLK, dual-SDO mode (default). See the 32-CLK, Dual-SDO Mode section.	32
32-CLK, single-SDO mode. See the 32-CLK, Single-SDO Mode section.	48
16-CLK, dual-SDO mode. See the 16-CLK, Dual-SDO Mode section.	16
16-CLK, single SDO mode. See the 16-CLK, Single SDO Mode section.	32

If $\overline{\text{CS}}$ is brought high before providing N SCLK falling edges, the write operation attempted in the frame is not valid. Refer to the [Frame Abort, Reconversion, or Short-Cycling](#) section for more details.

8.5.2 Write to User Programmable Registers

The device features three user-programmable registers: the configuration register (CFR), the REFDAC_A register, and the REFDAC_B register. These registers can be written with the device SDI pin. The first 16 bits of data on SDI are latched into the device on the first 16 SCLK falling edges. However, the new configuration takes effect only when the read or write operation is validated. If these registers are not required to update, SDI must remain low during the respective frames.

The first four SDI data bits (B[15:12]) determine what operation is performed (that is, either a read or write operation or no operation), which register address the operation uses, and the function of the next 12 SDI data bits (B[11:0]). [Table 4](#) lists the various combinations supported for B[15:12].

Table 4. Data Write Operation

B15	B14	B13	B12	OPERATION	FUNCTION OF BITS B[11:0]
0	0	0	0	No operation is performed	These bits are ignored
0	0	0	1	REFDAC_A read	000h; see the Reading User-Programmable Registers section
0	0	1	0	REFDAC_B read	000h; see the Reading User-Programmable Registers section
0	0	1	1	CFR read	000h; see the Reading User-Programmable Registers section
1	0	0	0	CFR write	See the Configuration Register (CFR) section
1	0	0	1	REFDAC_A write	See the REFDAC_A section
1	0	1	0	REFDAC_B write	See the REFDAC_B section
1	0	1	1	No operation is performed	These bits are ignored
X	1	X	X	No operation is performed	These bits are ignored

8.5.2.1 Configuration Register (CFR)

The device operation configuration is controlled by the configuration register (CFR) status. Data written into the CFR in a valid frame (F) determine the device configuration for frame (F+1). The bit functions are outlined in [Figure 87](#). On power-up, all bits in the CFR default to 0.

Figure 87. CFR Bit Functions

15	14	13	12	11	10	9	8
WRITE/READ	0	ADDR1	ADDR0	RD_CLK_MODE	RD_DATA_LINES	INPUT_RANGE	0
7	6	5	4	3	2	1	0
0	REF_SEL	STANDBY	0	0	0	0	0

Table 5. Configuration Register (CFR) Field Descriptions

Bit	Field	Type	Reset	Description
15	WRITE/READ	W	0h	These bits select the user-programmable register. 1000 = Select this combination to write to the CFR register and to enable bits 11:0
14	0	R/W	0h	
13	ADDR1	R/W	0h	
12	ADDR0	R/W	0h	
11	RD_CLK_MODE	R/W	0h	This bit provides clock mode selection for the serial interface. 0 = Selects 32-CLK mode (default) 1 = Selects 16-CLK mode (Note that the ADS8354 only supports 32-CLK mode. This bit is ignored for the ADS8354.)
10	RD_DATA_LINES	R/W	0h	This bit provides data line selection for the serial interface. 0 = Use SDO_A to output ADC_A data and SDO_B to output of ADC_B data (default) 1 = Use only SDO_A to output of ADC_A data followed by ADC_B data
9	INPUT_RANGE	R/W	0h	This bit selects the maximum input range for the ADC as a function of the reference voltage provided to the ADC. See the Analog Inputs section for more details. 0 = FSR equals $\pm V_{REF}$ 1 = FSR equals $\pm 2 \times V_{REF}$
8:7	0	R/W	0h	This bit must be set to 0 (default)
6	REF_SEL	R/W	0h	This bit selects the ADC reference voltage source. Refer to the Reference section for more details. 0 = Use external reference (default) 1 = Use internal reference
5	STANDBY	W	0h	This bit is used by the device to enter or exit STANDBY mode. Refer to the STANDBY Mode section for more details.
4	0	R/W	0h	This bit must be set to 0 (default)
3:0	0	R/W	0h	These bits must be set to 0 (default)

8.5.2.2 REFDAC Registers (REFDAC_A and REFDAC_B)

The REFDAC registers, bit functions, and resolution information are described in this section.

Figure 88. REFDAC_X Bit Functions

15	14	13	12	11	10	9	8

064 to 000	000	Do not use

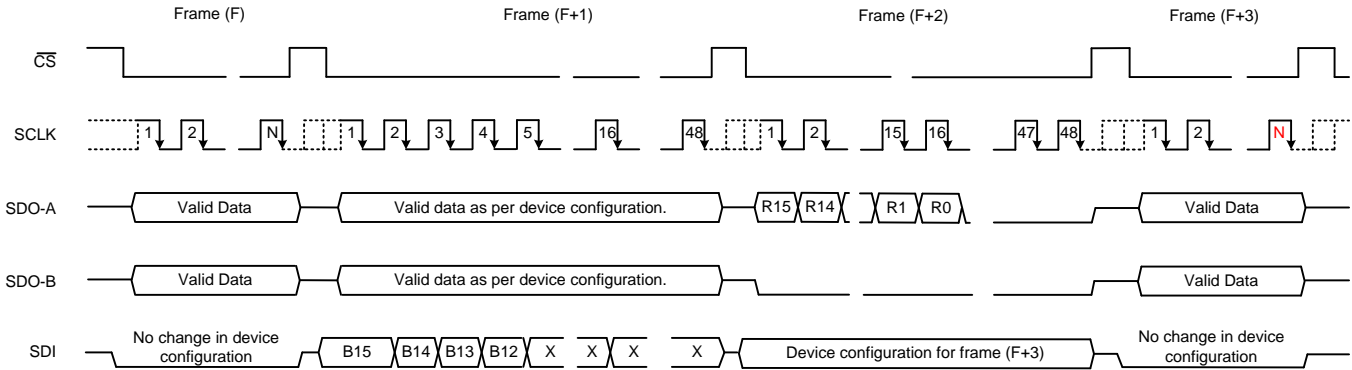

(1) Actual output voltage may vary by a few millivolts from the specified value. To obtain the desired output voltage, TI recommends starting with the specified register setting and then experimenting with five codes on either side of the specified register setting.

8.5.3 Data Read Operation

The device supports two types of read operations: reading user-programmable registers and reading conversion results.

8.5.3.1 Reading User-Programmable Registers

The device supports a readback option for all user-programmable registers: CFR, REFDAC_A, and REFDAC_B. Figure 89 shows a detailed timing diagram for this operation.

Note that *N* is a function of the device configuration, as described in Table 3.

Figure 89. Register Readback Timing

To readback the user-programmable register settings, the appropriate control word should be transmitted to the device during frame (F+1), as shown in Table 8. Frame (F+1) must have at least 48 SCLK falling edges.

Table 8. Control Word to Readback User-Programmable Registers

USER-PROGRAMMABLE REGISTER	CONTROL WORD TO BE PROGRAMMED IN FRAME (F+1)	
	B[15:12] (Binary)	B[11:0] (Hex)
CFR	0011b	000h
REFDAC_A	0001b	000h
REFDAC_B	0010b	000h

Frame (F+2) must have at least 48 SCLK falling edges. During frame (F+2), SDO_A outputs the contents of the selected user-programmable register on the first 16 SCLK falling edges (as shown in Table 9) and then outputs 0s for any subsequent SCLK falling edges. The SDO_B pin outputs 0s for all the SCLK falling edges.

Table 9. Register Data Read Back

USER-PROGRAMMABLE REGISTER	DATA READ ON SDO-A IN FRAME (F+2)									
	R15	R14	R13	R12	R11	—	R3	R2	R1	R0
CFR	0	0	1	1	CFG.B11	—	CFG.B3	CFG.B2	CFG.B1	CFG.B0
REFDAC_A	0	0	0	1	REFDAC_A.D8	—	REFDAC_A.D0	0	0	0
REFDAC_B	0	0	1	0	REFDAC_B.D8	—	REFDAC_B.D0	0	0	0

Register settings programmed during frame (F+2) determine the device configuration in frame (F+3).

8.5.3.2 Conversion Data Read

The device provides four different interface modes to the user for reading the conversion result. These modes offer flexible hardware connections and firmware programming. Table 10 shows how to select one of the four interface modes.

Table 10. Interface Mode Selection

CFR.B11	CFR.B10	INTERFACE MODE	MINIMUM SCLK FALLING EDGES REQUIRED TO VALIDATE WRITE OPERATION N
0	0	32-CLK, dual-SDO mode (default)	32
0	1	32-CLK, single-SDO mode	48
1	0	16-CLK, dual-SDO mode	16
1	1	16-CLK, single SDO mode	32

In the 32-CLK interface modes, the device uses an internal clock to convert the sampled analog signal. The conversion is completed during the first 16 periods of SCLK and the conversion result can be read on the subsequent SCLK falling edges. All devices in the family (that is, ADS8354, ADS7854, and ADS7254) support the 32-CLK interface modes.

In addition to the 32-CLK interface modes, the ADS7854 and ADS7254 also support the 16-CLK interface modes. By using the 16-CLK interface modes, the same throughput can be achieved at much lower SCLK speeds.

The following sections detail the various interface modes supported by the device.

8.5.3.2.1 32-CLK, Dual-SDO Mode (CFR.B11 = 0, CFR.B10 = 0, Default)

The 32-CLK, dual-SDO mode is the default mode supported by all devices. This mode can also be selected by writing CFR.B11 = 0 and CFR.B10 = 0.

In this mode, the SDO_A pin outputs the ADC_A conversion result and the SDO_B pin outputs the ADC_B conversion result. Figure 90 shows a detailed timing diagram for this mode.

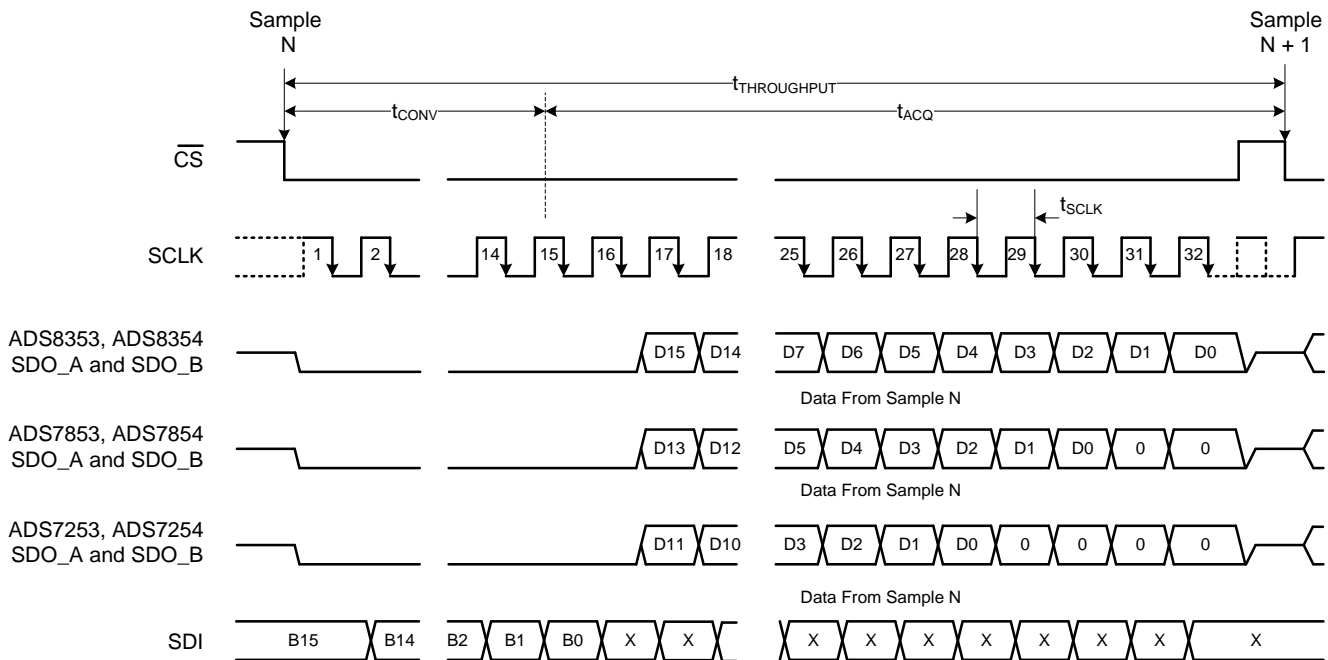

Figure 90. 32-CLK, Dual-SDO Mode Timing Diagram

A \overline{CS} falling edge brings the serial data bus out of 3-state and also outputs a 0 on the SDO_A and SDO_B pins. The device converts the sampled analog input during the conversion time (t_{CONV}). SDO_A and SDO_B read 0 during this period. After completing the conversion process, the sample-and-hold circuit returns to sample mode. The device outputs the MSBs of ADC_A and ADC_B on SDO_A and SDO_B pins, respectively, on the 16th SCLK falling edge. The subsequent SCLK falling edges are used to shift out the rest of the bits of the conversion result, as shown in [Table 11](#).

Table 11. Data Launch Edge

DEVICE	PINS	LAUNCH EDGE												
		\overline{CS}	SCLK											\overline{CS}
		↓	↓1	—	↓15	↓16	—	↓27	↓28	↓29	↓30	↓31	↓32 ...	↑
ADS8354	SDO-A	0	0	—	0	D15_A	—	D4_A	D3_A	D2_A	D1_A	D0_A	0 ...	Hi-Z
	SDO-B	0	0	—	0	D15_B	—	D4_B	D3_B	D2_B	D1_B	D0_B	0 ...	Hi-Z
ADS7854	SDO-A	0	0	—	0	D13_A	—	D2_A	D1_A	D0_A	0	0	0 ...	Hi-Z
	SDO-B	0	0	—	0	D13_B	—	D2_B	D1_B	D0_B	0	0	0 ...	Hi-Z
ADS7254	SDO-A	0	0	—	0	D11_A	—	D0_A	0	0	0	0	0 ...	Hi-Z
	SDO-B	0	0	—	0	D11_B	—	D0_B	0	0	0	0	0 ...	Hi-Z

In this mode, at least 32 SCLK falling edges must be given to validate the read or write frame. A \overline{CS} rising edge ends the frame and puts the serial bus into 3-state.

Refer to [Table 12](#) for timing specifications specific to this serial interface mode.

Table 12. 32-CLK, Dual-SDO Interface Specific Timing

PARAMETER	TEST CONDITIONS	MIN	TYP	MAX	UNIT

		ADS7254	450		ns

8.5.3.2.2 32-CLK, Single-SDO Mode (CFR.B11 = 0, CFR.B10 = 1)

The 32-CLK, single-SDO mode provides the option of using only one SDO pin (SDO_A) to read conversion results from both ADCs (ADC_A and ADC_B). SDO_B remains in 3-state and can be treated as a no connect (NC) pin.

This mode can be selected by writing CFR.B11 = 0 and CFR.B10 = 1. Figure 91 shows a detailed timing diagram for this mode.

Figure 91. 32-CLK, Single-SDO Mode Timing Diagram

A \overline{CS} falling edge brings the serial data bus out of 3-state and also outputs a 0 on the SDO_A pin. The device converts the sampled analog input during the conversion time (t_{CONV}). SDO_A reads 0 during this period. After completing the conversion process, the sample-and-hold circuit goes back into sample mode. The device outputs the MSB of ADC_A on the SDO_A pin on the 16th SCLK falling edge. The subsequent SCLK falling edges are used to shift out the conversion result of ADC_A followed by the conversion result of ADC_B on the SDO_A pin, as shown in Table 13.

Table 13. Data Launch Edge

DEVICE	PIN	LAUNCH EDGE																			
		\overline{CS}		SCLK																\overline{CS}	
		↓	↓1	—	↓15	↓16	—	↓27	↓28	↓29	↓30	↓31	↓32	—	↓43	↓44	↓45	↓46	↓47	↓48 ...	↑

8.5.3.2.3 16-CLK, Dual-SDO Mode (CFR.B11 = 1, CFR.B10 = 0)

The 16-CLK, dual-SDO mode is designed to support the maximum throughput at lower SCLK frequencies. This interface mode is not supported by the ADS8354.

For the ADS7854 and ADS7254, this interface mode can be selected by writing CFR.B11 = 1 and CFR.B10 = 0. In this mode, the SDO_A pin outputs the ADC_A conversion result and the SDO_B pin outputs the ADC_B conversion result. Figure 92 shows a detailed timing diagram for this mode.

Figure 92. 16-CLK, Dual-SDO Mode Timing Diagram

A \overline{CS} falling edge brings the serial data bus out of 3-state and also outputs a 0 on the SDO_A and SDO_B pins. The subsequent SCLK falling edges are used for conversion and for data transfer using the serial interface, as shown in [Table 15](#).

The sample-and-hold circuit goes back into sample mode as soon as the conversion process is over.

Table 15. Data Launch Edge

DEVICE	PINS	LAUNCH EDGE								
		\overline{CS}	SCLK							\overline{CS}
		↓	↓1	↓2	—	↓13	↓14	↓15	↓16 ...	↑
ADS7854	SDO-A	0	0	D13_A	—	D2_A	D1_A	D0_A	0 ...	Hi-Z
	SDO-B	0	0	D13_B	—	D2_B	D1_B	D0_B	0 ...	Hi-Z
ADS7254	SDO-A	0	0	D11_A	—	D0_A	0	0	0 ...	Hi-Z
	SDO-B	0	0	D11_B	—	D0_B	0	0	0 ...	Hi-Z

In this mode, at least 16 SCLK falling edges must be given to validate the read or write frame. A \overline{CS} rising edge ends the frame and puts the serial bus into 3-state.

Refer to [Table 16](#) for timing specifications specific to this serial interface mode.

Table 16. 16-CLK, Dual-SDO Interface Specific Timing

PARAMETER	TEST CONDITIONS	MIN	TYP	MAX	UNIT
TIMING REQUIREMENTS					
t_{CLK}	CLOCK period	ADS7854	55.5		ns
		ADS7254	55.5		ns

		ADS7254		$12 \times t_{CLK}$	ns

8.5.3.2.4 16-CLK, Single-SDO Mode (CFR.B11 = 1, CFR.B10 = 1)

The 16-CLK, single-SDO mode provides the option of using only one SDO pin (SDO_A) and a lower-speed clock to read the conversion results of both ADCs. This interface mode is not supported by the ADS8354.

For the ADS7854 and ADS7254, this mode can be selected by writing CFR.B11 = 1 and CFR.B10 = 1. The SDO_A pin is used to output the conversion results of both ADCs (ADC_A and ADC_B). SDO_B remains in 3-state and can be treated as a no connect (NC) pin. Figure 93 shows a detailed timing diagram for this mode.

Figure 93. 16-CLK, Single-SDO Mode Timing Diagram

A \overline{CS} falling edge brings the serial data bus out of 3-state and also outputs a 0 on the SDO_A pin. The subsequent SCLK falling edges are used for conversion and for data transfer using the serial interface, as shown in Table 17.

The sample-and-hold circuit goes back into sample mode as soon as the conversion process is over.

Table 17. Data Launch Edge

DEVICE	PIN	LAUNCH EDGE															
		\overline{CS}	SCLK													\overline{CS}	
		↓	↓1	↓2	—	↓13	↓14	↓15	↓16	↓17	↓18	—	↓29	↓30	↓31	↓32 ...	↑
ADS7854	SDO-A	0	0	D13_A	—	D2_A	D1_A	D0_A	0	0	D13_B	—	D2_B	D1_B	D0_B	0 ...	Hi-Z
ADS7254	SDO-A	0	0	D11_A	—	D0_A	0	0	0	0	D11_B	—	D0_B	0	0	0 ...	Hi-Z

In this mode, at least 32 SCLK falling edges must be given to validate the read/write frame. A \overline{CS} rising edge ends the frame and puts the serial bus into 3-state.

Refer to [Table 18](#) for timing specifications specific to this serial interface mode.

8.5.4 Low-Power Modes

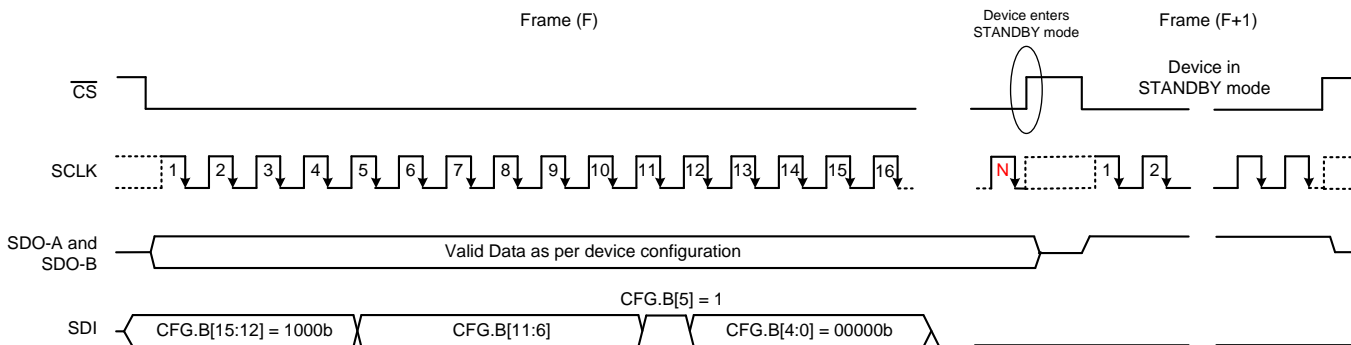

In normal mode of operation, all internal circuits of the device are always powered up and the device is always ready to commence a new conversion. This mode enables the device to support the rated throughput. The device also supports two low-power modes to optimize the power consumption at lower throughputs: STANDBY mode and software power-down (SPD) mode.

8.5.4.1 STANDBY Mode

The device supports a STANDBY mode of operation where some of the internal circuits of the device are powered down. However, if bit 6 in configuration register is set to 1 (CFR.B6 = 1), then the internal reference is not powered down and the contents of the REFDAC_A and REFDAC_B registers are retained to enable faster power-up to a normal mode of operation.

As shown in [Figure 94](#), a valid write operation in frame (F) to program the configuration register with B5 set to 1 (CFR.B5 = 1) places the device into a STANDBY mode of operation on the following \overline{CS} rising edge. While in STANDBY mode, SDO_A and SDO_B output all 1s when \overline{CS} is low and remain in 3-state when \overline{CS} is high.

To remain in STANDBY mode, SDI must remain low in the subsequent frames.

Note that N is a function of the device configuration, as described in [Table 3](#).

Figure 94. Enter STANDBY Mode

As shown in [Figure 95](#), a valid write operation in frame (F+3) by writing the configuration register with B5 set to 0 (CFR.B5 = 0) brings the device out of STANDBY mode on the following $\overline{\text{CS}}$ rising edge. Frame (F+3) must have at least 48 SCLK falling edges.

After exiting the STANDBY mode, a delay of $t_{\text{PU_STDBY}}$ must elapse for the internal circuits to fully power-up and resume normal operation in frame (F+4). Device configuration for frame (F+4) is determined by the status of the CFR.B[11:6] bits programmed during frame (F+3).

Note that N is a function of the device configuration, as described in [Table 3](#).

Figure 95. Exit STANDBY Mode

Refer to the [Timing Characteristics: Serial Interface](#) for timing specifications for this operating mode.

8.5.4.2 Software Power-Down (SPD) Mode

In software power-down (SPD) mode, all internal circuits (including the internal references) are powered down. However, the contents of the REFDAC_A and REFDAC_B registers are retained.

As shown in [Figure 96](#), to enter SPD mode, the device must be selected (by bringing \overline{CS} low) and SDI must be kept high for a minimum of 48 SCLK cycles during frame (F). The device goes to SPD on the \overline{CS} rising edge following frame (F). While in SPD mode, SDO_A and SDO_B go to 3-state irrespective of the status of the \overline{CS} signal.

To remain in SPD mode, SDI must remain high in subsequent frames.

Figure 96. Enter SPD Mode

As shown in [Figure 97](#), to exit SPD mode, the device must be selected (by bringing \overline{CS} low) and SDI must be kept low for a minimum of 48 SCLK cycles during frame (F+3). The device starts powering-up on a \overline{CS} rising edge following frame (F+3). After frame (F+3), a delay of t_{PU_SPD} must elapse before programming the configuration register.

A valid write operation in frame (F+4) sets the device configuration for frame (F+5). Frame (F+4) must have at least 48 SCLK falling edges. The output data in frame (F+4) should be discarded.

Note that N is a function of the device configuration, as described in [Table 3](#).

Figure 97. Exit SPD Mode

Refer to the [Timing Characteristics: Serial Interface](#) for timing specifications for this operating mode.

8.5.5 Frame Abort, Reconversion, or Short-Cycling

As discussed in Figure 98, the minimum number of SCLK falling edges (N) that must be provided between the beginning and end of the frame depends on the serial interface mode. The SCLK falling edges (N) program the device and retrieve the conversion result. If $\overline{\text{CS}}$ is brought high before the expected number of SCLK falling edges are provided, the current frame is aborted and the device starts sampling the new analog input signal.

If frame (F) is aborted, then the register write operation attempted in frame (F) is considered invalid and the internal registers are not updated. The device continues to have the same configuration in frame (F+1) from frame (F).

The output data bits latched before the $\overline{\text{CS}}$ rising edge are still valid data that correspond to sample N.

Figure 98. Frame Abort, Reconversion, or Short-Cycling Feature

Refer to the [Timing Characteristics: Serial Interface](#) for timing specifications for this operating mode.

9 Application and Implementation

9.1 Application Information

The two primary circuits required to maximize the performance of a high-precision, successive approximation register (SAR), analog-to-digital converter (ADC) are the input driver and the reference driver circuits. This section details some general principles for designing these circuits, and some application circuits designed using these devices.

The device supports operation either with an internal or external reference source. Refer to the [Reference](#) section for details about the decoupling requirements.

The reference source to the ADC must provide low-drift and very accurate dc voltage and support the dynamic charge requirements without affecting the noise and linearity performance of the device. The output broadband noise (typically in the order of a few 100 μV_{RMS}) of the reference source must be appropriately filtered by using a low-pass filter with a cutoff frequency of a few hundred hertz. After band-limiting the noise from the reference source, the next important step is to design a reference buffer that can drive the dynamic load posed by the reference input of the ADC. At the start of each conversion, the reference buffer must regulate the voltage of the reference pin within 1 LSB of the intended value. This condition necessitates the use of a large filter capacitor at the reference pin of the ADC. The amplifier selected to drive the reference input pin must be stable while driving this large capacitor and should have low output impedance, low offset, and temperature drift specifications. To reduce the dynamic current requirements and crosstalk between the channels, a separate reference buffer is recommended for driving the reference input of each ADC channel.

The input driver circuit for a high-precision ADC mainly consists of two parts: a driving amplifier and a fly-wheel RC filter. The amplifier is used for signal conditioning of the input voltage and its low output impedance provides a buffer between the signal source and the switched capacitor inputs of the ADC. The RC filter helps attenuate the sampling charge injection from the switched-capacitor input stage of the ADC and functions as an antialiasing filter to band-limit the wideband noise contributed by the front-end circuit. Careful design of the front-end circuit is critical to meet the linearity and noise performance of a high-precision ADC.

9.1.1 Input Amplifier Selection

Selection criteria for the input amplifiers is highly dependent on the input signal type and the performance goals of the data acquisition system. Some key amplifier specifications to consider while selecting an appropriate amplifier to drive the inputs of the ADC are:

- *Small-signal bandwidth.* Select the small-signal bandwidth of the input amplifiers to be as high as possible after meeting the power budget of the system. Higher bandwidth reduces the closed-loop output impedance of the amplifier, thus allowing the amplifier to more easily drive the low cutoff frequency RC filter at the ADC inputs. Higher bandwidth also minimizes the harmonic distortion at higher input frequencies. In order to maintain the overall stability of the input driver circuit, the amplifier bandwidth should be selected as described in [Equation 8](#):

$$\text{Unity - Gain Bandwidth} \geq 4 \times \left(\frac{1}{2\pi \times (R_{FLT} + R_{FLT}) \times C_{FLT}} \right) \quad (8)$$

- *Noise.* Noise contribution of the front-end amplifiers should be as low as possible to prevent any degradation in SNR performance of the system. As a rule of thumb, to ensure that the noise performance of the data acquisition system is not limited by the front-end circuit, the total noise contribution from the front-end circuit should be kept below 20% of the input-referred noise of the ADC. Noise from the input driver circuit is band-limited by designing a low cutoff frequency RC filter and is calculated by [Equation 9](#):

$$N_G \times \sqrt{2} \times \sqrt{\left(\frac{V_{1/f_AMP_PP}}{6.6} \right)^2 + e_{n_RMS}^2 \times \frac{\pi}{2} \times f_{-3dB}} \leq \frac{1}{5} \times \frac{V_{REF}}{\sqrt{2}} \times 10^{-\left(\frac{SNR(dB)}{20} \right)}$$

where:

- V_{1/f_AMP_PP} is the peak-to-peak flicker noise in μV ,
- e_{n_RMS} is the amplifier broadband noise density in $\text{nV}/\sqrt{\text{Hz}}$,
- f_{-3dB} is the 3-dB bandwidth of the RC filter, and
- N_G is the noise gain of the front-end circuit, which is equal to 1 in a buffer configuration. (9)

Application Information (continued)

- **Distortion.** Both the ADC and the input driver introduce nonlinearity in a data acquisition block. As a rule of thumb, to ensure that the distortion performance of the data acquisition system is not limited by the front-end circuit, the distortion of the input driver should be at least 10 dB lower than the distortion of the ADC, as shown in Equation 10.

$$\text{THD}_{\text{AMP}} \leq \text{THD}_{\text{ADC}} - 10 \text{ (dB)} \quad (10)$$

- **Settling Time.** For dc signals with fast transients that are common in a multiplexed application, the input signal must settle to the desired accuracy at the inputs of the ADC during the acquisition time window. This condition is critical to maintain the overall linearity performance of the ADC. Typically, the amplifier data sheets specify the output settling performance only up to 0.1% to 0.001%, which may not be sufficient for the desired accuracy. Therefore, the settling behavior of the input driver should always be verified by TINA™-SPICE simulations before selecting the amplifier.

9.1.2 Antialiasing Filter

Converting analog-to-digital signals requires sampling an input signal at a constant rate. Any higher frequency content in the input signal beyond half the sampling frequency is digitized and folded back into the low-frequency spectrum. This process is called *aliasing*. Therefore, an analog, antialiasing filter must be used to remove the harmonic content from the input signal before being sampled by the ADC. An antialiasing filter is designed as a low-pass, RC filter, for which the 3-dB bandwidth is optimized based on specific application requirements. For dc signals with fast transients (including multiplexed input signals), a high-bandwidth filter is designed to allow accurately settling the signal at the ADC inputs during the small acquisition time window. For ac signals, the filter bandwidth should be kept low to band-limit the noise fed into the ADC input, thereby increasing the signal-to-noise ratio (SNR) of the system.

A filter capacitor, C_{FLT} , connected across the ADC inputs (as shown in Figure 99), filters the noise from the front-end drive circuitry, reduces the sampling charge injection and provides a charge bucket to quickly charge the internal sample-and-hold capacitors during the acquisition process. As a rule of thumb, the value of this capacitor should be at least 10 times the specified value of the ADC sampling capacitance. For these devices, the input sampling capacitance is equal to 40 pF. Thus, the value of C_{FLT} should be greater than 400 pF. The capacitor should be a COG- or NPO-type because these capacitor types have a high-Q, low-temperature coefficient, and stable electrical characteristics under varying voltages, frequency, and time.

Note that driving capacitive loads can degrade the phase margin of the input amplifiers, thus making the amplifier marginally unstable. To avoid amplifier stability issues, series isolation resistors (R_{FLT}) are used at the output of the amplifiers. A higher value of R_{FLT} is helpful from the amplifier stability perspective, but adds distortion as a result of interactions with the nonlinear input impedance of the ADC. Distortion increases with source impedance, input signal frequency, and input signal amplitude. Therefore, the selection of R_{FLT} requires balancing the stability and distortion of the design. For these devices, TI recommends limiting the value of R_{FLT} to a maximum of 22 Ω in order to avoid any significant degradation in linearity performance. The tolerance of the selected resistors can be chosen as 1% because the use of a differential capacitor at the input balances the effects resulting from any resistor mismatch.

Figure 99. Antialiasing Filter

The input amplifier bandwidth should be much higher than the cutoff frequency of the antialiasing filter. TI strongly recommends performing a SPICE simulation to confirm that the amplifier has more than 40° phase margin with the selected filter. If an amplifier has less than a 40° phase margin with 22-Ω resistors, using a different amplifier with higher bandwidth or reducing the filter cutoff frequency with a larger differential capacitor is advisable.

9.2 Typical Applications

9.2.1 DAQ Circuit to Achieve Maximum SINAD for a 10-kHz Input Signal at Full Throughput

NOTE: Only one ADC channel is shown in this diagram. Replicate the same circuit for other ADC channels.

Figure 100. DAQ Circuit: Maximum SINAD for a 10-kHz Input Signal at Full Throughput, 32-CLK Interface

NOTE: Only one ADC channel is shown in this diagram. Replicate the same circuit for other ADC channels.

Figure 101. DAQ Circuit: Maximum SINAD for a 10-kHz Input Signal at Full Throughput, 16-CLK Interface

(1) When using the REF5050, AVDD must be set to 5.5 V.

Figure 102. Reference Drive Circuit

Typical Applications (continued)

9.2.1.1 Design Requirements

To design an application circuit optimized to achieve target specifications listed in [Table 19](#).

Table 19. Target Specifications

TARGET SPECIFICATIONS		TEST CONDITIONS			
SNR	THD	DEVICE	INPUT SIGNAL FREQUENCY	THROUGHPUT	INTERFACE MODE
> 88 dB	< -100 dB	ADS8354	10 kHz	Maximum supported	32-CLK, dual-SDO
> 83.5 dB	< -95 dB	ADS7854	10 kHz	Maximum supported	32-CLK, dual-SDO
> 80.5 dB	< -88 dB	ADS7854	10 kHz	Maximum supported	16-CLK, dual-SDO
> 72.5 dB	< -88 dB	ADS7254	10 kHz	Maximum supported	32-CLK, dual-SDO
> 71.5 dB	< -85 dB	ADS7254	10 kHz	Maximum supported	16-CLK, dual-SDO

9.2.1.2 Detailed Design Procedure

Best practice is for the distortion from the input driver to be at least 10 dB less than the ADC distortion. The distortion resulting from variation in the common-mode signal is eliminated by using a fully-differential amplifier (FDA) that establishes a fixed common-mode level at the ADC input. The low-power [THS4521](#), used as an input driver, provides exceptional ac performance because of its extremely low-distortion and high-bandwidth specifications. The output common-mode voltage of the THS4521 is set by the voltage provided on its V_{OCM} pin. In addition, the components of the antialiasing filter are such that the noise from the front-end circuit is kept low without adding distortion to the input signal.

The application circuit illustrated in [Figure 100](#) is optimized to achieve the lowest distortion and lowest noise for a 10-kHz input signal fed to the ADS8354 or ADS7854 or ADS7254 operating at full throughput with the default 32-CLK, dual-SDO interface mode. The input signal is processed through a high-bandwidth, low-distortion, fully-differential amplifier and a low-pass RC filter before being fed into the device.

The ADS7854 and the ADS7254 also support 16-CLK interface modes that achieve the rated throughput rate at much lower SCLK frequencies. However, when using the 16-CLK interface modes, the device receives less acquisition time when compared to the 32-CLK interface modes. The application circuit illustrated in [Figure 101](#) is optimized to achieve the lowest distortion and lowest noise for a 10-kHz input signal fed to the ADS7854 or ADS7254 operating at full throughput with the 16-CLK, dual-SDO interface mode. The input signal is processed through a high-bandwidth, low-distortion, fully-differential amplifier and a low-pass RC filter before being fed into the device.

[Figure 102](#) illustrates the reference driver circuit when operation with an external reference is desired. The reference voltage is generated by the high-precision, low-noise [REF50xx](#) circuit. The output broadband noise of the reference is heavily filtered by a low-pass filter with a 3-dB cutoff frequency of 160 Hz. The decoupling capacitor on each reference pin is selected to be 10 μ F. The low output impedance, low noise, and fast settling time makes the [OPA2350](#) a good choice for driving this high capacitive load.

9.2.1.3 Application Curves

To minimize external components and to maximize the dynamic range of the ADC, device is configured to operate with internal reference (CFR.B6 = 1) and $\pm 2 \times V_{REF_X}$ input full scale range (CFR.B9 = 1).

Figure 103, Figure 104, and Figure 105, show the FFT plots and test results obtained with the ADS8354, ADS7854, and ADS7254, respectively, operating at full throughput with a 32-CLK interface and the circuit configuration of Figure 100.

Figure 106 and Figure 107 show the FFT plots and test results obtained with the ADS7854 and ADS7254, respectively, operating at full throughput with 16-CLK interface and the circuit configuration of Figure 101.

9.2.2 DAQ Circuit to Achieve Maximum SINAD for a 100-kHz Input Signal at Full Throughput

NOTE: Only one ADC channel is shown in this diagram. Replicate the same circuit for other ADC channels.

(1) The 330 pF capacitors are not required for ADS7854 and ADS7254.

Figure 108. DAQ Circuit: Maximum SINAD for a 100-kHz Input Signal at Full Throughput

(1) When using the REF5050, AVDD must be set to 5.5 V.

Figure 109. Reference Drive Circuit

9.2.2.1 Design Requirements

To design an application circuit optimized to achieve target specifications listed in [Table 20](#).

Table 20. Target Specifications

TARGET SPECIFICATIONS		TEST CONDITIONS			
SNR	THD	DEVICE	INPUT SIGNAL FREQUENCY	THROUGHPUT	INTERFACE MODE
> 86 dB	< -95 dB	ADS8354	100 kHz	Maximum supported	32-CLK, dual-SDO
> 81.5 dB	< -90 dB	ADS7854	100 kHz	Maximum supported	32-CLK, dual-SDO
> 79.5 dB	< -88 dB	ADS7854	100 kHz	Maximum supported	16-CLK, dual-SDO
> 72 dB	< -88 dB	ADS7254	100 kHz	Maximum supported	32-CLK, dual-SDO
> 71 dB	< -85 dB	ADS7254	100 kHz	Maximum supported	16-CLK, dual-SDO

9.2.2.2 Detailed Design Procedure

Best practice is for the distortion from the input driver to be at least 10 dB less than the ADC distortion. The distortion resulting from variation in the common-mode signal is eliminated by using a fully-differential amplifier (FDA) that establishes a fixed common-mode level at the ADC input. The low-power [THS4521](#), used as an input driver, provides exceptional ac performance because of its extremely low-distortion and high-bandwidth specifications. The output common-mode voltage of the THS4521 is set by the voltage provided on its V_{OCM} pin. In addition, the components of the antialiasing filter are such that the noise from the front-end circuit is kept low without adding distortion to the input signal.

The application circuit illustrated in [Figure 108](#) is optimized to achieve the lowest distortion and lowest noise for a 100-kHz input signal fed to the ADS8354 or ADS7854 or ADS7254 operating at full throughput. The input signal is processed through a high-bandwidth, low-distortion, fully-differential amplifier and a low-pass RC filter before being fed into the device.

[Figure 102](#) illustrates the reference driver circuit when operation with an external reference is desired. The reference voltage is generated by the high-precision, low-noise [REF50xx](#) circuit. The output broadband noise of the reference is heavily filtered by a low-pass filter with a 3-dB cutoff frequency of 160 Hz. The decoupling capacitor on each reference pin is selected to be 10 μ F. The low output impedance, low noise, and fast settling time makes the [OPA2350](#) a good choice for driving this high capacitive load.

9.2.2.3 Application Curves

To minimize external components and to maximize the dynamic range of the ADC, device is configured to operate with internal reference (CFR.B6 = 1) and $\pm 2 \times V_{REF_X}$ input full scale range (CFR.B9 = 1).

Figure 110, Figure 111, and Figure 112 show the FFT plots and test results obtained with the ADS8354, ADS7854 and ADS7254, respectively, operating at full throughput with a 32-CLK interface and the circuit configuration of Figure 108.

Figure 113 and Figure 114 show the FFT plots and test results obtained with the ADS7854 and ADS7254, respectively, operating with a 16-CLK interface and the circuit configuration of Figure 108.

10 Power-Supply Recommendations

The devices have two separate power supplies: AVDD and DVDD. The device operates on AVDD; DVDD is used for the interface circuits. AVDD and DVDD can be independently set to any value within the permissible ranges.

When using the device with $\pm 2 \times V_{REF}$ input range (CFR.B9 = 1), the AVDD supply voltage value defines the permissible voltage swing on the analog input pins. To avoid saturation of output codes, and to use the full dynamic range on the analog input pins, AVDD must be set as shown in [Equation 11](#), [Equation 12](#), and [Equation 13](#):

$$AVDD \geq 2 \times V_{REF_A} \quad (11)$$

$$AVDD \geq 2 \times V_{REF_B} \quad (12)$$

$$4.75 \text{ V} \leq AVDD \leq 5.25 \text{ V} \quad (13)$$

Decouple the AVDD and DVDD pins with the GND pin using individual 10- μ F decoupling capacitors, as shown in [Figure 115](#).

Figure 115. Power-Supply Decoupling

11 Layout

11.1 Layout Guidelines

Figure 116 shows a board layout example for the ADS8354, ADS7854, and ADS7254 with the WQFN package. Use a ground plane underneath the device and partition the PCB into analog and digital sections. Avoid crossing digital lines with the analog signal path and keep the analog input signals and the reference input signals away from noise sources. As shown in Figure 116, the analog input and reference signals are routed on the left side of the board and the digital connections are routed on the right side of the device.

The power sources to the device must be clean and well-bypassed. Use 10- μ F, ceramic bypass capacitors in close proximity to the analog (AVDD) and digital (DVDD) power-supply pins. Avoid placing vias between the AVDD and DVDD pins and the bypass capacitors. Connect all ground pins to the ground plane using short, low impedance paths.

The REFIO-A and REFIO-B reference inputs and outputs are bypassed with 10- μ F, X7R-grade, 0805-size, 16-V rated ceramic capacitors (C_{REF-x}). Place the reference bypass capacitors as close as possible to the reference REFIO-x pins and connect the bypass capacitors using short, low-inductance connections. Avoid placing vias between the REFIO-x pins and the bypass capacitors. Small 0.1- Ω to 0.2- Ω resistors (R_{REF-x}) are used in series with the reference bypass capacitors to improve stability.

The fly-wheel RC filters are placed immediately next to the input pins. Among ceramic surface-mount capacitors, COG (NPO) ceramic capacitors provide the best capacitance precision. The type of dielectric used in COG (NPO) ceramic capacitors provides the most stable electrical properties over voltage, frequency, and temperature changes. Figure 116 shows C_{IN-A} and C_{IN-B} filter capacitors placed across the analog input pins of the device.

12.3 Trademarks

TINA is a trademark of Texas Instruments Inc..
All other trademarks are the property of their respective owners.

12.4 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSELETE: TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

TBD: The Pb-Free/Green conversion plan has not been defined.

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

⁽³⁾ MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

⁽⁴⁾ There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

⁽⁵⁾ Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

⁽⁶⁾ Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

Important Information and Disclaimer:The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. THERMAL PAD MECHANICAL DATA

RTE (S-PWQFN-N16)

PLASTIC QUAD FLATPACK NO-LEAD

THERMAL INFORMATION

This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For information on the Quad Flatpack No-Lead (QFN) package and its advantages, refer to Application Report, QFN/SON PCB Attachment, Texas Instruments Literature No. SLUA271. This document is available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.

Bottom View

买方和在系统中整合 TI 产品的其他开发人员（总称“设计人员”）理解并同意，设计人员在设计应用时应自行实施独立的分析、评价和判断，且应全权负责并确保应用的安全性，及设计人员的应用（包括应用中使用的 TI 产品）应符合所有适用的法律法规及其他相关要求。设计人员就自己设计的应用声明，其具备制订和实施下列保障措施所需的一切必要专业知识，能够 (1) 预见故障的危险后果，(2) 监视故障及其后果，以及 (3) 降低可能导致危险的故障几率并采取适当措施。设计人员同意，在使用或分发包含 TI 产品的任何应用前，将彻底测试该等应用和该等应用中所用 TI 产品的功能。

TI 提供技术、应用或其他设计建议、质量特点、可靠性数据或其他服务或信息，包括但不限于与评估模块有关的参考设计和材料（总称“TI 资源”），旨在帮助设计人员开发整合了 TI 产品的应用，如果设计人员（个人，或如果是代表公司，则为设计人员的公司）以任何方式下载、访问或使用任何特定的 TI 资源，即表示其同意仅为该等目标，按照本通知的条款使用任何特定 TI 资源。

TI 所提供的 TI 资源，并未扩大或以其他方式修改 TI 对 TI 产品的公开适用的质保及质保免责声明；也未导致 TI 承担任何额外的义务或责任。TI 有权对其 TI 资源进行纠正、增强、改进和其他修改。除特定 TI 资源的公开文档中明确列出的测试外，TI 未进行任何其他测试。

设计人员只有在开发包含该等 TI 资源所列 TI 产品的应用时，才被授权使用、复制和修改任何相关 TI 资源。但并未依据禁止反言原则或其他法律授予您任何 TI 知识产权的任何其他明示或默示的许可，也未授予您 TI 或第三方的任何技术或知识产权的许可，该等许可包括但不限于任何专利权、版权、屏蔽作品权或与美国 TI 产品或服务的任何整合、机器制作、流程相关的其他知识产权。涉及或参考了第三方产品或服务的信息不构成使用此类产品或服务的许可或与其相关的保证或认可。使用 TI 资源可能需要您向第三方获得对该等第三方专利或其他知识产权的许可。

TI 资源系“按原样”提供。TI 兹免除对资源及其使用作出所有其他明确或默示的保证或陈述，包括但不限于对准确性或完整性、产权保证、无屡发故障保证，以及适销性、适合特定用途和不侵犯任何第三方知识产权的任何默认保证。TI 不负责任何申索，包括但不限于因组合产品所致或与之有关的申索，也不为或对设计人员进行辩护或赔偿，即使该等产品组合已列于 TI 资源或其他地方。对因 TI 资源或其使用引起或与之有关的任何实际的、直接的、特殊的、附带的、间接的、惩罚性的、偶发的、从属或惩戒性损害赔偿，不管 TI 是否获悉可能会产生上述损害赔偿，TI 概不负责。

除 TI 已明确指出特定产品已达到特定行业标准（例如 ISO/TS 16949 和 ISO 26262）的要求外，TI 不对未达到任何该等行业标准要求而承担任何责任。

如果 TI 明确宣称产品有助于功能安全或符合行业功能安全标准，则该等产品旨在帮助客户设计和创作自己的符合相关功能安全标准和要求的的应用。在应用内使用产品的行为本身不会配有安全特性。设计人员必须确保遵守适用于其应用的相关安全要求和标准。设计人员不可将任何 TI 产品用于关乎性命的医疗设备，除非已由各方获得授权的管理人员签署专门的合同对此类应用专门作出规定。关乎性命的医疗设备是指出现故障会导致严重身体伤害或死亡的医疗设备（例如生命保障设备、心脏起搏器、心脏除颤器、人工心脏泵、神经刺激器以及植入设备）。此类设备包括但不限于，美国食品药品监督管理局认定为 III 类设备的设备，以及在美国以外的其他国家或地区认定为同等类别设备的所有医疗设备。

TI 可能明确指定某些产品具备某些特定资格（例如 Q100、军用级或增强型产品）。设计人员同意，其具备一切必要专业知识，可以为自己的应用选择适合的产品，并且正确选择产品的风险由设计人员承担。设计人员单方面负责遵守与该等选择有关的所有法律或监管要求。

设计人员同意向 TI 及其代表全额赔偿因其不遵守本通知条款和条件而引起的任何损害、费用、损失和/或责任。
