1.00 Introduction

This application note describes how µC/OS-II has been ported to the Microchip dsPIC33 family of processors. This application note does not assume any specific dsPIC33 derivative.

Figure 1-1 shows a block diagram showing the relationship between your application, µC/OS-II, the port code and the BSP (Board Support Package). Relevant sections of this application note are referenced on the figure.

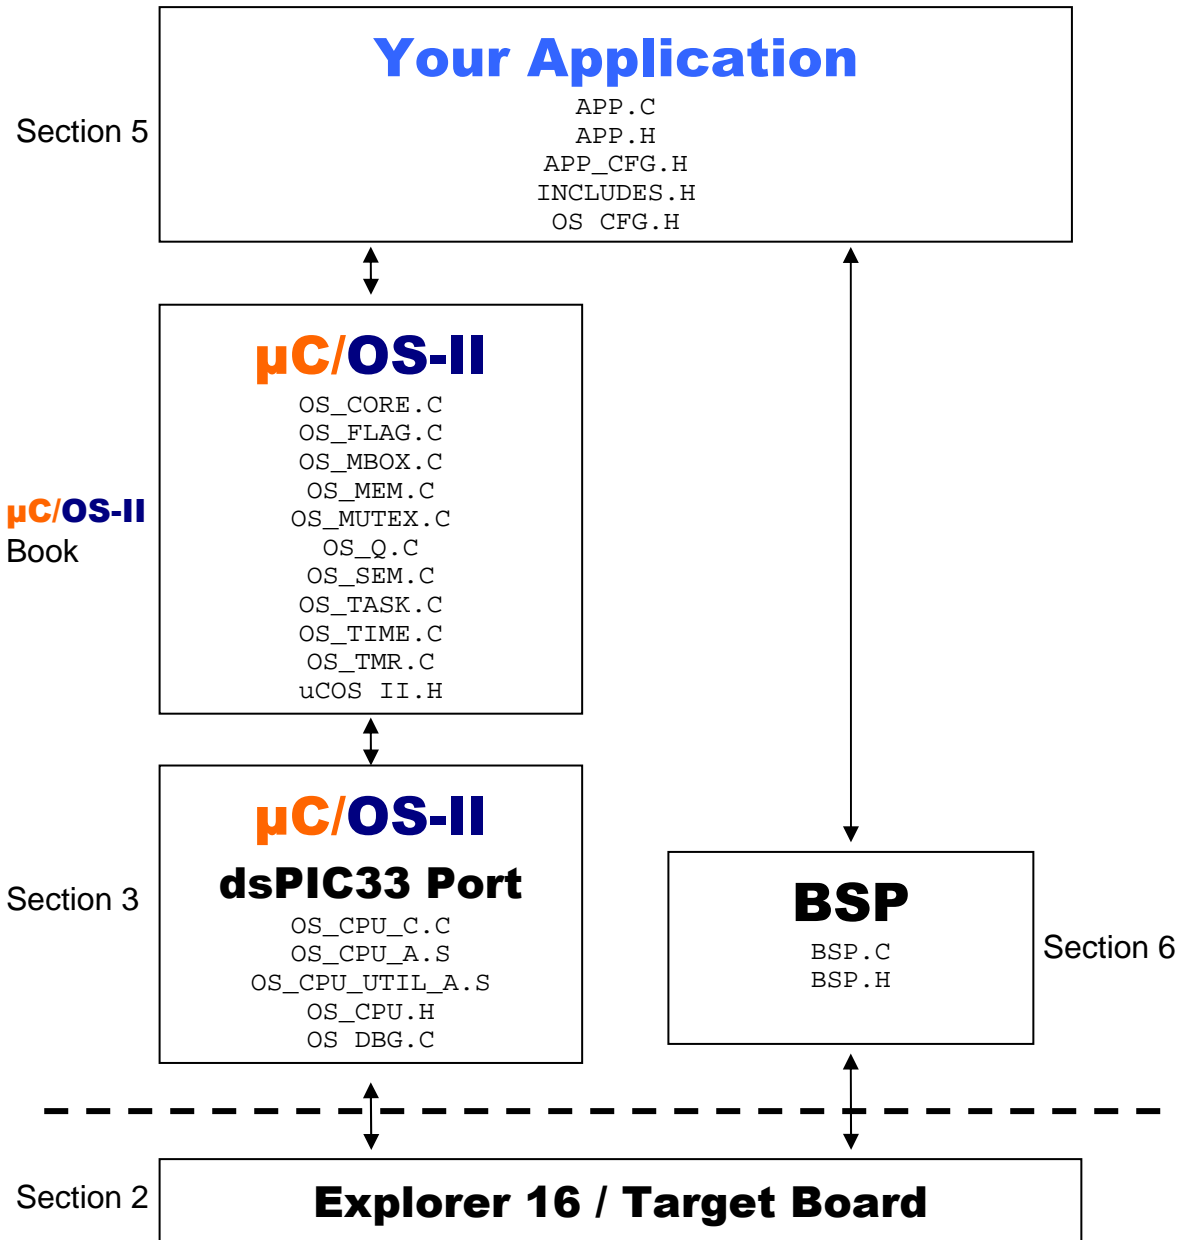

Figure 1-1, Relationship between modules.

2.00 The Microchip dsPIC33 programmer's model

This section provides a brief description of the dsPIC33 programmer's model. We present enough information in this section to provide a brief introduction. A complete description can be found in the Microchip documentation.

The dsPIC33 family of CPU cores features proprietary Microchip architecture and is designed for controller applications using a 16-bit (data), DSP capable architecture. Below are some of the features of the dsPIC33 family of CPU cores:

- 16 General-purpose 'Working' registers
- Dual 40 bit Accumulators, 17x17 Multiplier
- 24 bit variable length instruction word, 23 bit program counter.
- 40 bit barrel shifter capable of 16 bit shift left or shift right in 1 cycle.
- Dedicated 1KB of DMA Ram
- Hardware divider support
- Dual Address generators for accessing memory blocks X and Y.
- High speed deterministic interrupt processing

The dsPIC33 is a **Little Endian** architecture and thus the least significant byte of a value is placed at a lower memory location than its most significant byte.

Figure 2-1 shows the register model of the dsPIC33 and consist of 16 Working registers, two 40 bit accumulators, the Data Table Page register, the Program Space Visibility Page Address register, a Repeat Loop Counter, three dedicated DO Loop registers, the Core Configuration register, and a CPU Status register.

W0-W15 (Working Registers)

- Registers W0-W3 are general purpose scratch pad registers
- Registers W4-W7 are the DSP Operand registers
- Registers W8-W11 are the DSP address registers
- Register W12 doubles as the DSP Offset register
- Register W13 doubles as the DSP Write Back register
- Register W14 doubles as the Frame Pointer register
- Register W15 doubles as the CPU Stack Pointer register

The stack pointer always points to the last **pushed** element. In other words, when an element is pushed onto the stack, the stack pointer is first decremented and the value placed at the current location where the stack is pointing to. The stack is **popped** by first reading the contents of the stack and then incrementing the stack pointer.

SPLIM (Stack Pointer Limit Register)

- Causes a TRAP error when W15 is greater than SPLIM

ACCA / ACCB (DSP Accumulators)

- Dual 40 bit accumulators for DSP operations

TBLPAGE (Table Page Register)

- The 8-bit Table Page register (TBLPAG) is used to define a 32K word region within the program space. This is concatenated with a 16-bit effective address in order to arrive at a full 24-bit program space address.

PSVPAG (Program Space Visibility Page Address Register)

- For remapping operations, the 8-bit Program Space Visibility register (PSVPAG) is used to define a 16K word page in the program space. When the Most Significant bit of the EA is '1', PSVPAG is concatenated with the lower 15 bits of the EA to form a 23-bit program space address. Unlike table operations, this limits remapping operations strictly to the user memory area.

RCOUNT (Repeat Loop Counter)

- The RCOUNT register tracks the iteration count of an instruction that must be executed repetitively until its operation has been completed. Divide instructions are iterative instructions that make extensive use of the RCOUNT register.

DCOUNT (Do Loop Counter)

- Counts the iteration number of a DO loop

DOSTART (Do Loop Start Address)

- Holds the start address of a particular DO loop

DOEND (Do Loop End Address)s

- Holds the end address of a particular DO loop

CORECON (Core Configuration Register)

- Contains configuration bits pertaining to how the processor handles certain types of operations.

STATUS (CPU Status Register)

- Contains status CPU status flags indicating the state of the CPU after a given instruction.

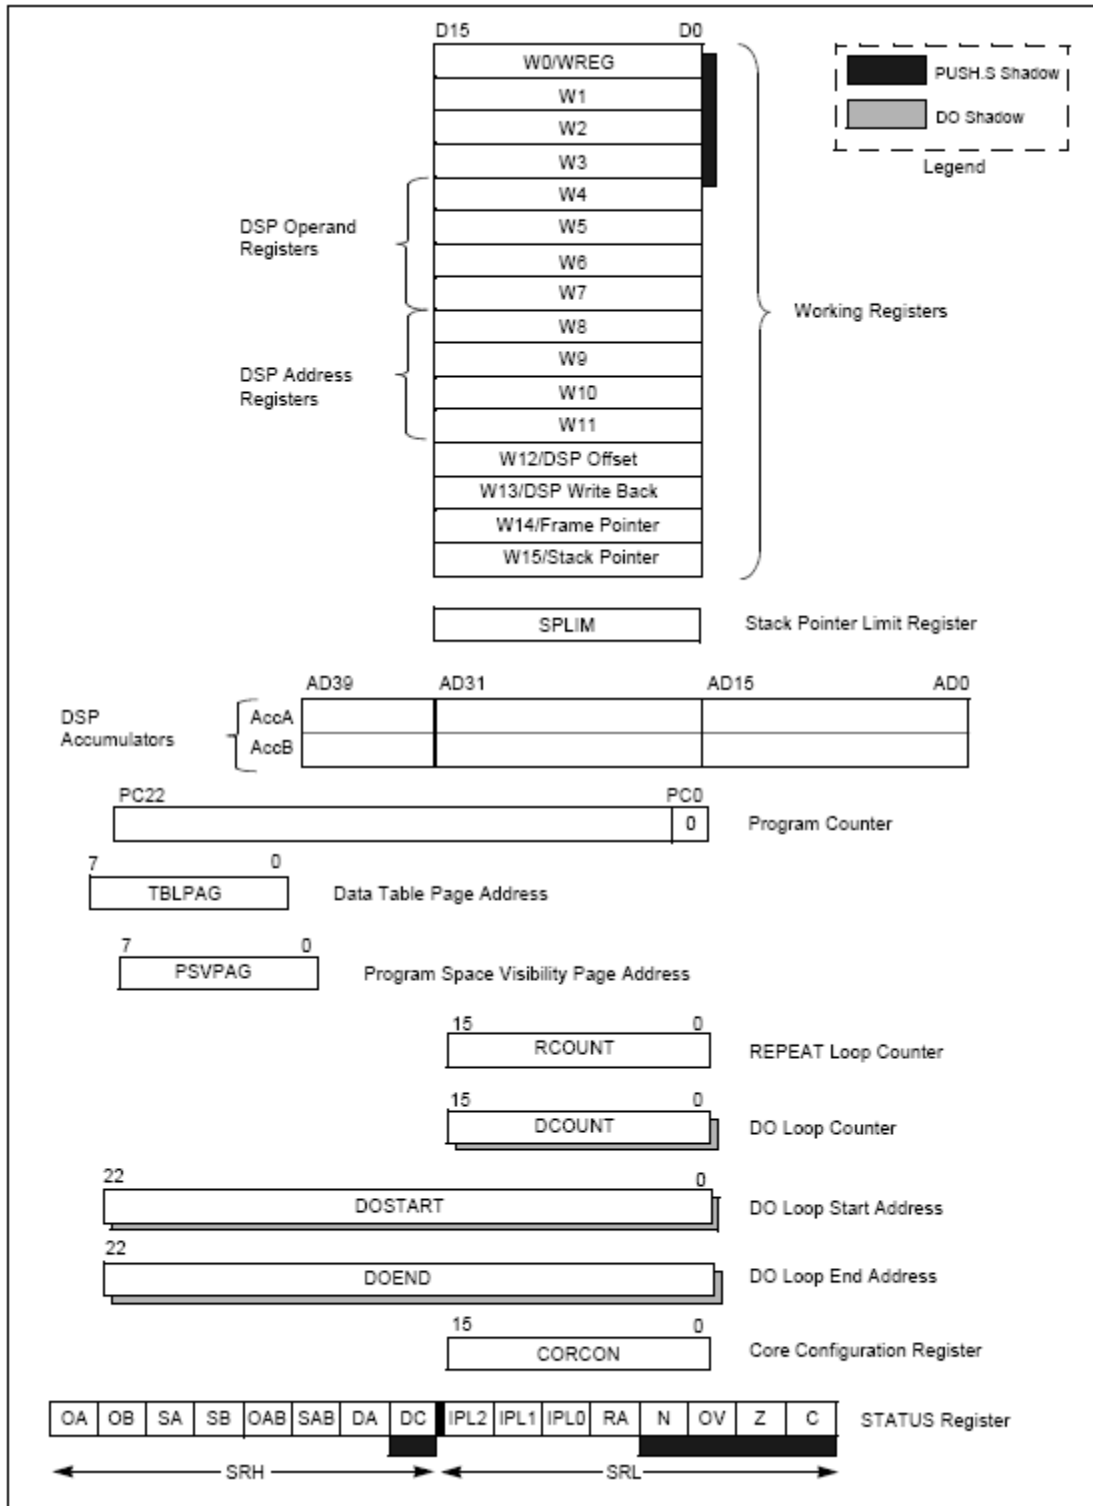

Figure 2-1, dsPIC33 Programmers Model.

3.00 μC/OS-II Port for dsPIC33

μC/OS-II has been ported to the Microchip C30, Hi-Tech dsPICC, and IAR iccDSPIC compilers. All ports currently utilize the MPLAB development environment v7.60 or greater. We strongly recommend checking with your compiler vendor to ensure that you have obtained the latest MPLAB IDE plug-in version available for the compiler of choice.

We used an Explorer 16 EVB with a dsPIC33FJ256GP710 dsPIC33 derivative to test the described application. It is assumed that you have **μC/OS-II** V2.82 or higher.

Various tool-chains require different extensions for assembly files. This document refers to assembly files having the extension '.s' in order to be consistent with the Microchip C30 tool-chain. However, in practice, the Hi-Tech dsPICC compiler uses the extension '.as' while the IAR iccDSPIC compiler uses '.s59'. Files from different tool-chain ports are not interchangeable.

3.01 Directories and Files

The software that accompanies this application note is assumed to be placed within the following directory depending on the tool-chain used:

C30:

`\Micrium\Software\uCOS-II\Ports\Microchip\PIC33FJ256\MPLAB_C30`

dsPICC:

`\Micrium\Software\uCOS-II\Ports\Microchip\PIC33FJ256\MPLAB_HT-DSPICC`

iccDSPIC:

`\Micrium\Software\uCOS-II\Ports\Microchip\PIC33FJ256\MPLAB_IAR`

The source code for the **μC/OS-II** dsPIC33 port is found in the following files:

<code>OS_CPU.H</code>	Section 3.02
<code>OS_CPU_C.C</code>	Section 3.03
<code>OS_CPU_A.S</code>	Section 3.04
<code>OS_CPU_UTIL_A.S</code>	Section 3.05
<code>OS_DBG.C</code>	Section 3.06

3.02 OS_CPU.H

OS_CPU.H contains processor- and implementation-specific #defines constants, macros, and typedefs.

3.02.01 OS_CPU.H, macros for ‘externals’

OS_CPU_GLOBALS and OS_CPU_EXT allows us to declare global variables that are specific to this port. However, this port does not contain any global variables but the declarations have been included in case we need to add some in the future.

Listing 3-1, OS_CPU.H, Globals and Externs

```
#ifndef OS_CPU_GLOBALS
#define OS_CPU_EXT
#else
#define OS_CPU_EXT extern
#endif
```

3.02.02 OS_CPU.H, Data Types

Listing 3-2, OS_CPU.H, Data Types

```
typedef unsigned char    BOOLEAN;
typedef unsigned char    INT8U;
typedef signed char      INT8S;
typedef unsigned int     INT16U;           (1)
typedef signed int       INT16S;
typedef unsigned long    INT32U;
typedef signed long      INT32S;
typedef float            FP32;             (2)
typedef long double      FP64;

typedef unsigned int     OS_STK;           (3)
typedef unsigned int     OS_CPU_SR;       (4)
```

- L3-2(1) If you were to consult the MPLab compiler documentation, you would find that an `int` is 16 bits, an `long` is 32 bits.
- L3-2(2) Floating-point data types are included even though µC/OS-II doesn't make use of floating-point numbers.
- L3-2(3) A stack entry for the dsPIC33 processor is always 16 bits wide; thus, `OS_STK` is declared accordingly. All task stacks must be declared using `OS_STK` as its data type.
- L3-2(4) The status register (STATUS) on the dsPIC33 processor is 16 bits wide. The `OS_CPU_SR` data type is used when `OS_CRITICAL_METHOD #3` is used (described below). In fact, this port only supports `OS_CRITICAL_METHOD #3` because it's the preferred method for µC/OS-II ports.

3.02.03 OS_CPU.H, Critical Sections

µC/OS-II, as with all real-time kernels, needs to disable interrupts in order to access critical sections of code and re-enable interrupts when done. **µC/OS-II** defines two macros to disable and enable interrupts: `OS_ENTER_CRITICAL()` and `OS_EXIT_CRITICAL()`, respectively. **µC/OS-II** defines three ways to disable interrupts but, you only need to use one of the three methods for disabling and enabling interrupts. The book (MicroC/OS-II, The Real-Time Kernel) describes the three different methods. The one to choose depends on the processor and compiler. In most cases, the preferred method is `OS_CRITICAL_METHOD #3`.

`OS_CRITICAL_METHOD #3` implements `OS_ENTER_CRITICAL()` by writing a function that will save the status register of the CPU in a variable. `OS_EXIT_CRITICAL()` invokes another function to restore the status register from the variable. We recommend that you name the functions expected in `OS_ENTER_CRITICAL()` and `OS_EXIT_CRITICAL()` as `OS_CPU_SR_Save()` and `OS_CPU_SR_Restore()`, respectively. These routines are generally stored in `OS_CPU_A.ASM`, however, in this case, since the registers are memory mapped, it makes sense to simply write and read to and from SR directly from C code.

Listing 3-3, OS_CPU.H, `OS_ENTER_CRITICAL()` and `OS_EXIT_CRITICAL()`

```
#define OS_CRITICAL_METHOD    3

#if OS_CRITICAL_METHOD == 3
#define OS_ENTER_CRITICAL()  {cpu_sr = SR; SRbits.IPL = 7;}
#define OS_EXIT_CRITICAL()   {SR      = cpu_sr;}
#endif
```

3.02.04 OS_CPU.H, Stack growth

The stacks on the dsPIC33 grows from low to high memory and thus, `OS_STK_GROWTH` is set to 0 to indicate this to **µC/OS-II**.

Listing 3-4, OS_CPU.H, Stack Growth

```
#define OS_STK_GROWTH    0
```

3.02.05 OS_CPU.H, Task Level Context Switch

Task level context switches are performed when **µC/OS-II** invokes the macro `OS_TASK_SW()`. Because context switching is processor specific, `OS_TASK_SW()` needs to execute an assembly language function. You should note that **µC/OS-II** disables all interrupts before calling `OSCtxSw()`.

Listing 3-5, OS_CPU.H, Task Level Context Switch

```
#define OS_TASK_SW()    OSCtxSw()
```

3.02.06 OS_CPU.H, Function Prototypes

As of V2.77, the prototypes for `OSCtxSw()`, `OSIntCtxSw()` and `OSStartHighRdy()` need to be placed in `OS_CPU.H`. In fact, it makes sense to do this since these are all port specific files.

Listing 3-8, OS_CPU.H, Function Prototypes

```
void      OSCtxSw(void);
void      OSIntCtxSw(void);
void      OSStartHighRdy(void);
```

3.03 OS_CPU_C.C

A µC/OS-II port requires that you write ten (10) fairly simple C functions:

```
OSInitHookBegin()
OSInitHookEnd()
OSTaskCreateHook()
OSTaskDelHook()
OSTaskIdleHook()
OSTaskStatHook()
OSTaskStkInit()
OSTaskSwHook()
OSTCBInitHook()
OSTimeTickHook()
```

Typically, µC/OS-II only requires `OSTaskStkInit()`. The other functions allow you to extend the functionality of the OS with your own functions.

IMPORTANT

You will also need to set the #define constant `OS_CPU_HOOKS_EN` to 1 in `OS_CFG.H` in order for the compiler to use the functions declared in this file.

3.03.01 OS_CPU_C.C, OSInitHookBegin()

This function is called by µC/OS-II's `OSInit()` at the very beginning of `OSInit()`. It gives the opportunity to add additional initialization code specific to the port. In this case, we initialize the global variable (global to `OS_CPU_C.C`) `OSTmrCtr`, which is used by the `OS_TMR.C` module if `OS_TMR_EN` is set to 1. Additionally, since µC/OS-II does not currently support the stack checking feature of the dsPIC33, the `SPLIM` register is set to a maximum value in RAM for compiler libraries that pre-initialize the `SPLIM` register during the start-up code.

Listing 3-9, OS_CPU_C.C, OSInitHookEnd()

```
void OSInitHookBegin (void)
{
    #if OS_TMR_EN > 0
        OSTmrCtr = 0;
    #endif

    SPLIM    =    0xFFFFE;
}
```

3.03.02 OS_CPU_C.C, OSInitHookEnd()

This function is called by **µC/OS-II**'s `OSInit()` at the very end of `OSInit()`. It gives the opportunity to add additional initialization code specific to the port. In this port, we stop measuring the interrupt disable time.

Listing 3-10, OS_CPU_C.C, OSInitHookEnd()

```
void OSInitHookEnd (void)
{
    #if OS_CPU_INT_DIS_MEAS_EN > 0
        OS_CPU_IntDisMeasInit();
    #endif
}
```

3.03.03 OS_CPU_C.C, OSTaskCreateHook()

This function is called by **µC/OS-II**'s `OSTaskCreate()` or `OSTaskCreateExt()` when a task is created. `OSTaskCreateHook()` gives the opportunity to add code specific to the port when a task is created. In our case, we call an application hook defined within `app.c` or `app_hooks.c`. The placement of the application hooks is non critical and may vary depending on project developer.

Listing 3-11, OS_CPU_C.C, OSInitHookEnd()

```
#if OS_CPU_HOOKS_EN > 0
void OSTaskCreateHook (OS_TCB *ptcb)
{
    #if OS_APP_HOOKS_EN > 0
        App_TaskCreateHook(ptcb);
    #else
        (void)ptcb;
    #endif
}
#endif
```

3.03.04 OS_CPU_C.C, OSTaskStkInit()

Recall (from the μC/OS-II documentation) that a task is declared as shown in listing 3-12.

Listing 3-12, μC/OS-II Task

```
void MyTask (void *p_arg)
{
    /* Do something with 'p_arg', optional */
    while (1) {
        /* Task body */
        OSTimeDlyHMSM(0, 0, 1, 0);
    }
}
```

The code in Listing 3-13 initializes the stack frame for the task being created. The task received an optional argument 'p_arg'. Most compilers pass a single argument in register w0 and thus, 'p_arg' is passed in w0 when the task is created.

The 'Task Body' MUST call either one of the OS???Pend() functions or OSTimeDly???() functions. In other words, a task MUST always be waiting for an event to occur. An event can be the reception of a signal or a message from another task or ISR. An event can also be to wait for the passage of time.

Listing 3-13, OS_CPU_C.C, OSTaskStkInit()

```
OS_STK *OSTaskStkInit (void (*task)(void *pd), void *p_arg, OS_STK *ptos, INT16U opt)
{
    INT16U x;
    INT8U  pc_high;

    pc_high = 0;

    *ptos++ = (OS_STK)task;           // Push the PC (Starting Address for the new task)
    *ptos++ = (OS_STK)pc_high;        // Upper byte word of start address

    *ptos++ = (OS_STK)task;           // Simulate an Interrupt, Push the PC

    x      = 0;                       // Set SR to enable all interrupts
    if (CORCONbits.IPL3) {             // Check the interrupt level mask bit IPL3, == 1?
        x |= 0x0080;                 // Save the value of IPL3 in x, bit 7.
    }

    *ptos++ = (OS_STK)(x | (INT16U)pc_high); // Push the SR Low, CORCON IPL3 and PC (22..16)

    *ptos++ = x;                      // Push SR Low and CORCON IPL3 on to the stack

    *ptos++ = (OS_STK)p_arg;           // W0, Push a dummy argument on to the stack
    *ptos++ = 0x1111;                 // W1
    *ptos++ = 0x2222;                 // W2
    *ptos++ = 0x3333;                 // W3
    *ptos++ = 0x4444;                 // W4
    *ptos++ = 0x5555;                 // W5
    *ptos++ = 0x6666;                 // W6
    *ptos++ = 0x7777;                 // W7
    *ptos++ = 0x8888;                 // W8
    *ptos++ = 0x9999;                 // W9
    *ptos++ = 0xAAAA;                 // W10
    *ptos++ = 0xBBBB;                 // W11
    *ptos++ = 0xCCCC;                 // W12
    *ptos++ = 0xDDDD;                 // W13
    *ptos++ = 0xEEEE;                 // W14

    *ptos++ = ACCAL;                  // Accumulator A
    *ptos++ = ACCAH;                  // Accumulator A
    *ptos++ = ACCAU;                  // Accumulator A

    *ptos++ = ACCBL;                  // Accumulator B
    *ptos++ = ACCBH;                  // Accumulator B
    *ptos++ = ACCBU;                  // Accumulator B

    *ptos++ = TBLPAG;                 // Table Page
    *ptos++ = PSVPAG;                 // Program Space Visibility Page Address
    *ptos++ = RCOUNT;                // Repeat Loop Counter

    *ptos++ = DCOUNT;                // Do Loop Counter
    *ptos++ = DOSTARTL;                // Do Loop Start Address
    *ptos++ = DOSTARTH;                // Do Loop Start Address
    *ptos++ = DOENDL;                 // Do Loop End Address
    *ptos++ = DOENDH;                 // Do Loop End Address

    *ptos++ = 0;                      // Status Register (contents irrelevant)
    *ptos++ = CORCON;                 // Core Configuration Register

    return (ptos);                   // Return the address to the top of the stack
}
```

Figure 3-1 shows how the stack frame is initialized for each task when it's created.

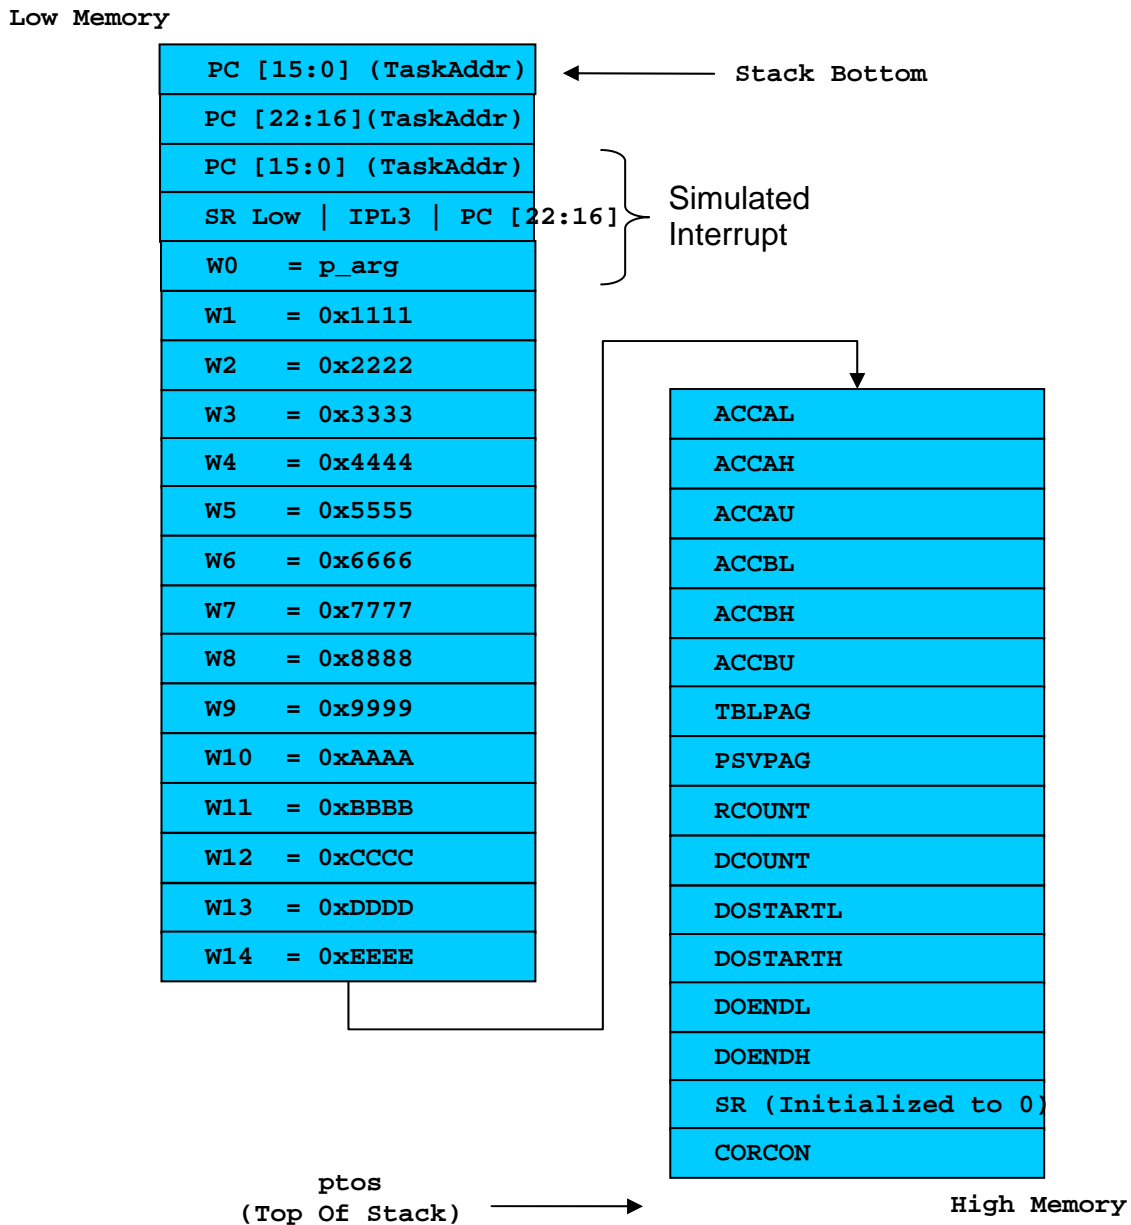

Figure 3-1, The Initial Stack Frame for each Task.

When the task is created, the final value of `ptos` is placed in the `OS_TCB` of that task by the **μC/OS-II** function that calls `OSTaskStkInit()` (i.e. `OSTaskCreate()` or `OSTaskCreateExt()`).

3.03.05 OS_CPU_C.C, OSTaskSwHook()

OSTaskSwHook() is called when a context switch occurs. This function allows the port code to be extended and do things such as measuring the execution time of a task, output a pulse on a port pin when a context switch occurs, etc. In our case, we call an application hook defined within `app.c` or `app_hooks.c`. The placement of the application hooks is non critical and may vary depending on project developer.

Listing 3-14, OS_CPU_C.C, OSCtxSwHook()

```
#if OS_CPU_HOOKS_EN > 0
void OSTaskSwHook (void)
{
    #if OS_APP_HOOKS_EN > 0
        App_TaskSwHook();
    #endif
}
#endif
```

3.03.06 OS_CPU_C.C, OSTimeTickHook()

OSTimeTickHook() is called at the very beginning of OSTimeTick(). This function allows the port code to be extended. Much like the other hooks, this function calls a user defined application hook placed within `app.c` or `app_hooks.c` depending on the preference of the project developer.

Additionally, OSTimeTickHook() determines whether it's time to update the **µC/OS-II** timers. This is done by signaling the timer task.

Listing 3-15, OS_CPU_C.C, OSTimeTickHook()

```
void OSTimeTickHook (void)
{
    #if OS_VIEW_MODULE > 0
        App_TimeTickHook();
    #endif

    #if OS_TMR_EN > 0
        OSTmrCtr++;
        if (OSTmrCtr >= (OS_TICKS_PER_SEC / OS_TMR_CFG_TICKS_PER_SEC)) {
            OSTmrCtr = 0;
            OSTmrSignal();
        }
    #endif
}
```

3.04 OS_CPU_A.S

A µC/OS-II port requires that you write five fairly simple assembly language functions. These functions are needed because you normally cannot save/restore registers from C functions. The five functions are:

```
OS_CPU_SR_Save()
OS_CPU_SR_Restore()
OSStartHighRdy()
OSCtxSw()
OSIntCtxSw()
```

It should be noted that since the dsPIC33 has memory mapped registers, the first two functions, namely OS_CPU_SR_Save() and OS_CPU_SR_Restore() have been implemented as C macros. Since the remaining functions involve modifying the program counter, they have been implemented in assembly language in order to leverage off of the RETFIE instruction. The RETFIE instruction will restore the PC from data located on the current tasks stack. This is why an interrupt is simulated during task stack initialization.

3.04.01 OS_CPU_A.S, OSStartHighRdy()

OSStartHighRdy() is called by OSStart() to start running the highest priority task that was created before calling OSStart(). OSStart() sets OSTCBHighRdy to point to the OS_TCB of the highest priority task.

Listing 3-18, OSStartHighRdy()

```
_OSStartHighRdy:
    call    _OSTaskSwHook                ; (1) Call user defined task switch hook

    mov     #0x0001, w0                  ; (2) Set OSRunning to TRUE
    mov.b   wreg, _OSRunning

    mov     _OSTCBHighRdy, w0            ; (3) Resume Stack Pointer
    mov     [w0], w15

    OS_REGS_RESTORE                     ; (4) Restore Context

    retfie                               ; (5) Run Task
```

- L3-18(1) Before starting the highest priority task, we call OSTaskSwHook() in case a hook function has been declared (see OS_CPU_C.C).
- L3-18(2) The µC/OS-II flag OSRunning is set to TRUE indicating that µC/OS-II will be running once the first task is started.
- L3-18(3) We then get the pointer to the task's top-of-stack (was stored by OSTaskCreate() or OSTaskCreateExt()). See figure 3-1 (ptos is stored in the OS_TCB of the created task).
- L3-18(4) We then pop all the registers from the task's stack. This is done by calling an assembly language macro which is declared in OS_CPU_UTIL_A.S and will be described later.
- L3-18(5) By executing a return from interrupt instruction, the dsPIC33 pops the PC and the STATUS register from the stack and thus, the dsPIC33 will start executing the task's code.

3.04.02 OS_CPU_A.S, OSCtxSw()

The code to perform a ‘task level’ context switch is shown below in pseudo-code. OSCtxSw() is called when a higher priority task is made ready to run by another task or, when the current task can no longer execute (e.g. it calls OSTimeDly(), OSSemPend() and the semaphore is not available, etc.).

A task level context switch occurs when µC/OS-II invokes the macro OS_TASK_SW() which, in the case of the dsPIC33 port, corresponds to calling OSCtxSw(). Normally, it is ideal to use a software interrupt or TRAP in order to enter OSCtxSw(), however, since a software interrupt is not available, code must adjust the stack frame in order to simulate an interrupt such that the RETFIE instruction may be used to restore the PC, SR Low, and CORCON IPL3.

```
OS_TASK_SW()
OSCtxSw:
    Add SRL, IPL3 and the upper 7 bits of the return PC to simulate an ISR    /* (1) */

    Save the CPU registers onto the old task's stack;                        /* (2) */

    OSTCBCur->OSTCBStkPtr = SP;                                              /* (3) */
    OSTaskSwHook();                                                         /* (4) */
    OSPrioCur              = OSPrioHighRdy;                                /* (5) */
    OSTCBCur                = OSTCBHighRdy;                                /* (6) */
    SP                      = OSTCBHighRdy->OSTCBStkPtr;                    /* (7) */

    Restore the CPU registers from the new task's stack;                     /* (8) */

    Return from Interrupt;                                                   /* (9) */
```

The actual code for the task level context switch is shown in Listing 3-19.

Listing 3-19, OSCtxSw()

```
_OSCtxSw:
    mov.b    SRL, wreg                ; (1) Simulate an interrupt, save SRL and CORCON IPL3
    sl      w0, #8, w0
    btsc    CORCON, #IPL3
    bset     w0, #7;
    ior      w0, [--w15], w0
    mov      w0, [w15++]

    OS_REGS_SAVE                        ; (2) Save context of interrupted task

    mov      _OSTCBCur, w0              ; (3) OSTCBCur->OSTCBStkPtr = SP
    mov      w15, [w0]

    call     _OSTaskSwHook              ; (4) Call user defined task switch hook

    mov      _OSTCBHighRdy, w1          ; (5) OSPrioCur = OSPrioHighRdy
    mov      w1, _OSTCBCur

    mov.b    _OSPrioHighRdy, wreg       ; (6) OSTCBCur = OSTCBHighRdy
    mov.b    wreg, _OSPrioCur

    mov      [w1], w15                  ; (7) SP = OSTCBHighRdy->OSTCBStkPtr

    OS_REGS_RESTORE                    ; (8) Restore context of interrupted task

    retfie                               ; (9) Return from interrupt
```

3.04.03 OS_CPU_A.S, OSIntCtxSw()

When an ISR (Interrupt Service Routine) completes, OSIntExit() is called to determine whether a more important task than the interrupted task needs to execute. If that's the case, OSIntExit() determines which task to run next and calls OSIntCtxSw() to perform the actual context switch to that task. You will notice that OSIntCtxSw() is identical to the second half of OSCtxSw(). The reason we have these as two separate functions is to simplify debugging. Specifically, if you wanted to set a breakpoint in OSIntCtxSw(), you would hit the breakpoint during a task level context switch (if OSIntCtxSw() was just a label in OSCtxSw()). Of course this would make debugging a bit difficult.

Listing 3-20, OSIntCtxSw()

```

__OSIntCtxSw:
    call    _OSTaskSwHook          ; Call user defined task switch hook

    mov     _OSTCBHighRdy, w1      ; OSPrioCur = OSPrioHighRdy
    mov     w1, _OSTCBCur
    mov.b   _OSPrioHighRdy, wreg   ; OSTCBCur = OSTCBHighRdy
    mov.b   wreg, _OSPrioCur

    mov     [w1], w15              ; W15 (SP) = OSTCBHighRdy->OSTCBStkPtr

    OS_REGS_RESTORE                ; Restore context of interrupted task

    retfie                          ; Switch to the new context

```

3.04.04 OS_CPU_A.S, T2Interrupt()

Since the dsPIC uses a vectored interrupt controller, **ALL ISR's must follow the following format**. The example provided below is the actual OS Time Tick ISR for µC/OS-II. Generally, it is common practice to initialize the OS Tick timer from C code (BSP.C) and service the interrupt in assembly (BSP_A.S). From assembly, a C ISR Handler function may be called in order to handle more complex operations.

Note: T2Interrupt() is one of two possible OS Time Tick Interrupt vectors. The option to choose 1 of 2 possible timers to generate the OS Tick exists from within (BSP.H). If an alternate timer is selected the ISR code below will not run. See T4Interrupt below.

```

__T2Interrupt:
    OS_REGS_SAVE                    ; 1) Save processor registers

    inc.b   _OSIntNesting           ; 2) Call OSIntEnter() or increment OSIntNesting

    dec.b   _OSIntNesting, wreg     ; 3) Check OSIntNesting. if OSIntNesting == 1,
    bra     nz, T2_Cont             ; then save the stack pointer, otherwise jump
    mov     _OSTCBCur, w0           ; to T2_Cont.
    mov     w15, [w0]

T2_Cont:
    call    _OS_Tick_ISR_Handler    ; 4) Call YOUR ISR Handler (May be a C function).
    ; In this case, the OS Tick ISR Handler

    call    _OSIntExit              ; 5) Call OSIntExit()

    OS_REGS_RESTORE                ; 6) Restore registers

    retfie

```

3.04.05 OS_CPU_A.S, T4Interrupt()

Since the dsPIC uses a vectored interrupt controller, **ALL ISR's must follow the following format**. The example provided below is the actual OS Time Tick ISR for µC/OS-II. Generally, it is common practice to initialize the OS Tick timer from C code (BSP.C) and service the interrupt in assembly (BSP_A.S). From assembly, a C ISR Handler function may be called in order to handle more complex operations.

Note: T4Interrupt() is one of two possible OS Time Tick Interrupt vectors. The option to choose 1 of 2 possible timers to generate the OS Tick exists from within (BSP.H). If an alternate timer is selected the ISR code below will not run. See T2Interrupt above.

```

__T4Interrupt:
    OS_REGS_SAVE                ; 1) Save processor registers

    inc.b  _OSIntNesting        ; 2) Call OSIntEnter() or increment OSIntNesting

    dec.b  _OSIntNesting, wreg   ; 3) Check OSIntNesting. if OSIntNesting == 1,
    bra    nz, T4_Cont          ;     then save the stack pointer, otherwise jump
    mov    _OSTCBCur, w0        ;     to T2_Cont.
    mov    w15, [w0]

T4_Cont:
    call   _OS_Tick_ISR_Handler ; 4) Call YOUR ISR Handler (May be a C function).
                                ;     In this case, the OS Tick ISR Handler

    call   _OSIntExit           ; 5) Call OSIntExit()

    OS_REGS_RESTORE            ; 6) Restore registers

    retfie

```

3.05 OS_CPU_UTIL_A.S

OS_CPU_UTIL_A.S is an assembly language file that declares two macros used to save the context of the CPU. These macros are called OS_REGS_SAVE and OS_REGS_RESTORE and are declared as shown below.

```
.macro OS_REGS_SAVE
    push.d    w0
    push.d    w2
    push.d    w4
    push.d    w6
    push.d    w8
    push.d    w10
    push.d    w12
    push      w14

    push      ACCAL
    push      ACCAH
    push      ACCAU
    push      ACCBL
    push      ACCBH
    push      ACCBU
    push      TBLPAG
    push      PSVPAG
    push      RCOUNT
    push      DCOUNT
    push      DOSTARTL
    push      DOSTARTH
    push      DOENDL
    push      DOENDH

    push      SR
    push      CORCON
.endm

.macro OS_REGS_RESTORE
    pop      CORCON
    pop      SR

    pop      DOENDH
    pop      DOENDL
    pop      DOSTARTH
    pop      DOSTARTL
    pop      DCOUNT
    pop      RCOUNT
    pop      PSVPAG
    pop      TBLPAG
    pop      ACCBU
    pop      ACCBH
    pop      ACCBL
    pop      ACCAU
    pop      ACCAH
    pop      ACCAL

    pop      w14
    pop.d    w12
    pop.d    w10
    pop.d    w8
    pop.d    w6
    pop.d    w4
    pop.d    w2
    pop.d    w0
.endm
```

IMPORTANT

You **MUST** include a reference to this file when you write your ISRs (see section 4.00, Interrupt Handling). This is done by using the assembler directive `#include` as follows:

```
.include    "os_cpu_util_a.s"
```

3.06 OS_DBG.C

OS_DBG.C is a file that has been added in V2.62 to provide Kernel Aware debugger to extract information about μC/OS-II and its configuration. Specifically, OS_DBG.C contains a number of constants that are placed in ROM (code space) which the debugger can read and display. Unfortunately, the MPLab debugger is not μC/OS-II aware and thus this file is not needed but should be included in all builds for future reference.

4.00 Interrupt Handling

The dsPIC33 contains an interrupt and exception vector table which contains up to 54 entries. Each of these entries point to an interrupt or exception handler. For µC/OS-II, each of those interrupt handlers **MUST** be written in assembly language. In fact, only a portion must be in assembly language as shown in listing 4-1. Note that you **ONLY** need to change the portion in **RED** for your own ISR. The rest of the code is **IDENTICAL** from one ISR to the next. Of course, you will need to give a unique name to your ISRs.

Additionally, every tool-chain vendor has a unique method for placing interrupt code and setting interrupt vector table entries. At the time of this writing, the following methods are employed by each of the three tool-chain vendors supported. You may use `bsp_a.s` as an interrupt example if necessary.

C30:

```
.text (1)
.global __ISR_Name (2)

__ISR_Name: (3)
    ... code ... (4)
```

1. Place the remaining code below this point within the TEXT section
2. Prototype the name of the ISR Handler. Note that the ISR handler name has two underscores. One provided by the ISR routine programmer, and another by Microchip as part of the ISR naming convention.
3. Declare the ISR with the name specified in the Microchip MPLAB C30 Users Guide. (Document DS51284F, Page 100, table 7-1). This will tell the compiler to add the constant ISR address to the vector table by means of adding carefully placed constant data to the application binary.
4. Include the ISR code under the ISR name label.

dsPICC:

```
GLOBAL __ISR_Name (1)
psect vectors,class=VECTORS,delta=2 (2)
ORG 01Ch (3)
DDW __ISR_Name (4)
psect text,global,reloc=4,class=CODE,delta=2 (5)

__ISR_Name: (6)
    ... code ... (7)
```

1. Prototype the name of the ISR.
2. Specify the placement of the defined double word (4) to be within the VECTORS section.
3. Specify the address to place ISR vector address. This value must be the vector address as specified in the dsPIC33 datasheet, minus six. The subtraction of six is necessary since ORG directive is NOT absolute and is relative to the current section (VECTORS) which starts from an offset of 0x06 in the memory map. In this case 01Ch represents vector address 0x22, the Timer2 ISR vector address.
4. Declare a double word representing the address of the ISR to be placed in the specified address.
5. Place the remainder of the code within the file in the CODE segment.
6. Declare the ISR with the name of your choice.
7. Include the ISR code under the ISR name label.

iccDSPIC:

```

COMMON INTVEC:CODE:ROOT(2)      (1)
ORG    __ISR_Address * 2        (2)
DL      __ISR_Name / 2          (3)
RSEG CODE:CODE:ROOT(2)         (4)

PUBLIC __ISR_Name                (5)

__ISR_Name:                     (6)
... code ...                    (7)

```

1. Place the defined long data word in the INTVEC section.
2. Specify the address to store the following long word (24 bit). This must be the ISR vector address as specified in the datasheet, multiplied by two.
3. Declare a long word whose value is that of the ISR_Handler defined within the same file below. The address to be placed in the above memory address must be that of the ISR_Name divided by two. Additional vectors may be declared at this time before step 4.
4. Place the remainder of the code within the file in the CODE segment.
5. Prototype the ISR Name. Note that the ISR name has two underscores appended to the beginning. This is to maintain consistency with the C30 compiler port, but is not required.
6. Declare the ISR with the name of your choice.
7. Include the ISR code under the ISR name label.

Listing 4-1, Assembly Language ISR

```

_My_ISR:
    OS_REGS_SAVE                ; 1) Save processor registers

    inc.b    _OSIntNesting      ; 2) Call OSIntEnter() or increment OSIntNesting

    dec.b    _OSIntNesting, wreg ; 3) Check OSIntNesting. if OSIntNesting == 1,
    bra     nz, _My_ISR_1      ; then save the stack pointer, otherwise jump
    mov     _OSTCBCur, w0      ; to _My_ISR_1
    mov     w15, [w0]

_My_ISR_1:
    call     _My_ISR_Handler    ; 4) Call YOUR ISR Handler (May be a C function).
                                ; You MUST clear the interrupt source either
                                ; from within, or just after your ISR Handler.

    call     _OSIntExit         ; 5) Call OSIntExit()

    OS_REGS_RESTORE            ; 6) Restore registers

    retfie                     ; 7) Return to the interrupted task

```

- L4-1(1) You then **MUST** save all of the registers using the OS_REGS_SAVE macro.
- L4-1(2) You **MUST** increment µC/OS-II's interrupt nesting counter (OSIntNesting)
- L4-1(3) You **MUST** check to see whether this is the first nested ISR by checking if OSIntNesting got incremented to 1. If this is the first nested ISR level then you **MUST** save the stack pointer into the current task's OS_TCB.
- L4-1(4) You can now call your actual ISR handler which could be written in C. You don't have to write the handler in C but it's generally more readable and portable. You may optionally choose to clear the interrupt source from within your ISR handler, or you may do it before calling OSIntExit() from assembly.
- L4-1(5) When you are done handling the ISR (i.e. the code returns from My_ISR_Handler()), you **MUST** call OSIntExit(). OSIntExit() checks to see if this is the last nested ISR. If it is then OSIntExit() checks to see if a more important task has been made ready-to-run by the ISR (or any other nested ISRs). If a more important task is ready-to-run, OSIntExit() doesn't return but instead context switches to the more important task.
- L4-1(6) If the interrupted task is still the most important task to run then OSIntExit() returns and we simply need to restore the saved CPU registers in order to return to the interrupted task. To restore the registers, you **MUST** invoke the OS_REGS_RESTORE macro.
- L4-1(7) The RETFIE instruction **MUST** be executed to return program execution back to the interrupted task in the event that OSIntExit() does not force a context switch.

The pseudo-code for the C ISR handler is shown in Listing 4-2.

Listing 4-2, C ISR Handler

```
void My_ISR_Handler (void)
{
    /* (1) Don't forget to clear the interrupt source */
    /* (2) Enable interrupts if you want to allow nested interrupts */
    /* (3) Handle the interrupt using C */
    /* (4) Disable interrupts (if you enabled them) */
}
```

- L4-2(1) Don't forget to clear the interrupting device (i.e. acknowledge that you serviced the interrupt). Failure to do this will cause the ISR to be re-entered which may not be what you want.
- L4-2(2) As indicated, you may enable interrupts (by lowering the IPL level in the SR) if you want to allow nested interrupts.
- L4-2(3) You can now service the interrupting device using the C programming language (instead of doing that in assembly language).
- L4-2(4) If you disabled interrupts (see step #1) then you should disable them before returning to the caller of this function.

5.00 Application Code

Your application code can make use of the port presented in this application note as described in this section. Figure 5-1 shows a block diagram of the relationship between your application, μC/OS-II, the μC/OS-II port, the BSP (Board Support Package), the dsPIC CPU and the target hardware.

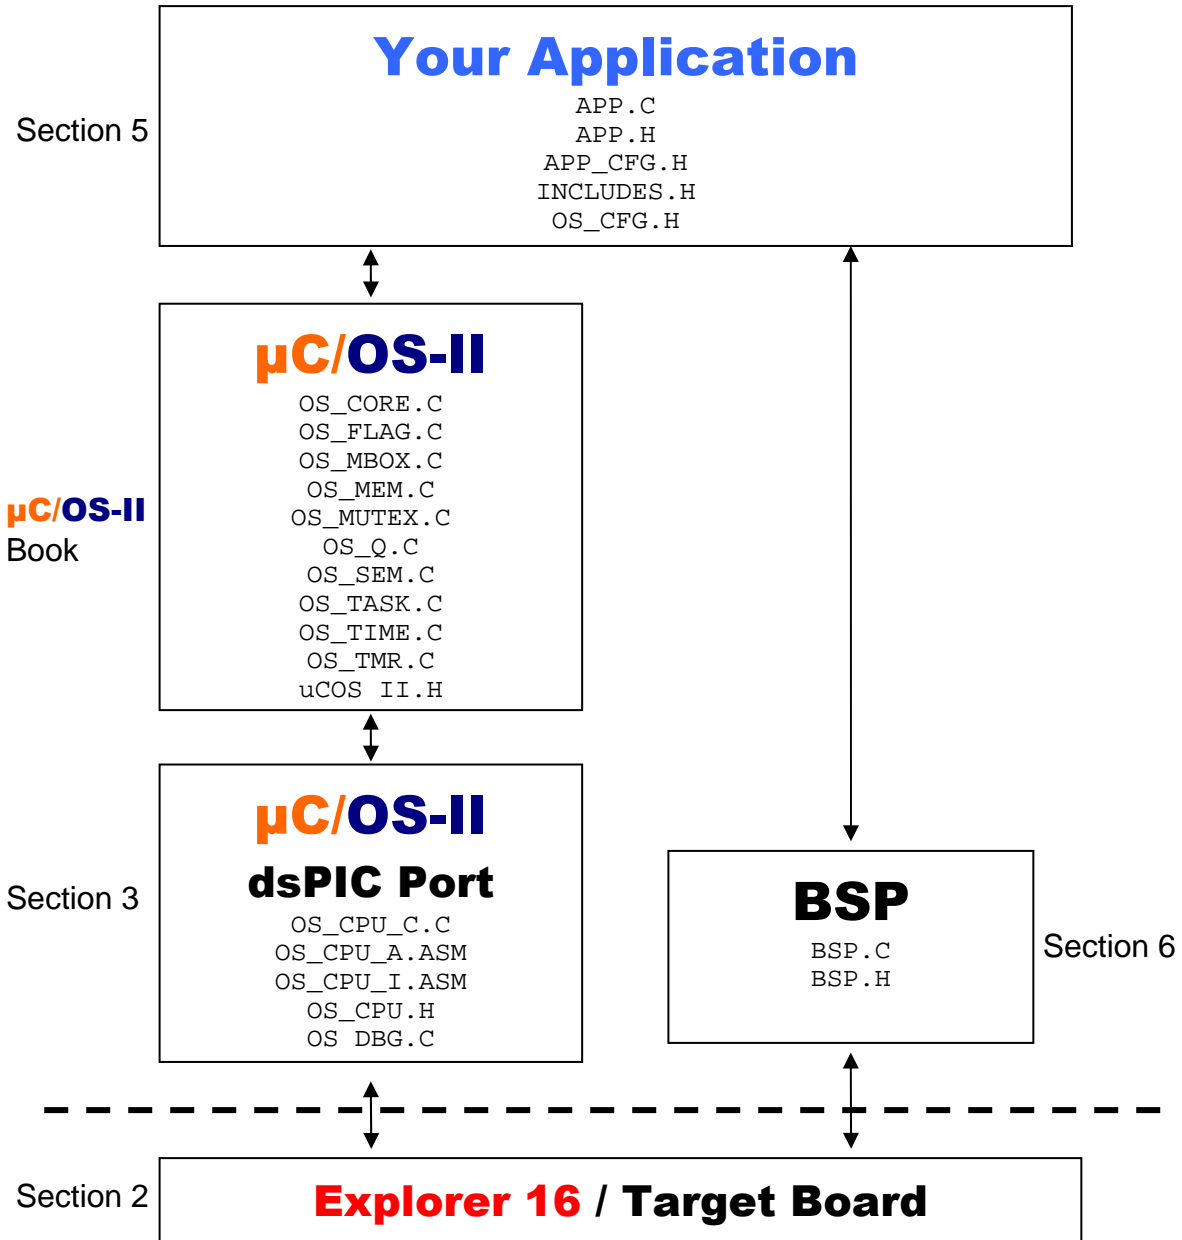

Figure 5-1, Relationship between modules.

5.01 APP.C, APP.H and APP_CFG.H

For sake of discussion, your application is placed in files called APP.C, APP.H and APP_CFG.H. Of course, your application (i.e. product) can contain many more files.

APP.C would be where you would place `main()` but, of course, you can place `main()` anywhere you want.

APP.H contains `#define` constants, macros, prototypes, etc. that are specific to your application. This file may NOT exist in YOUR application and it is not included in examples provided for the PIC.

APP_CFG.H contains `#define` constants to configure the application. We placed task stack sizes task priorities and other `#defines` in this file. This allows you to locate task priorities and sizes in one place.

APP.C is a standard test file for **µC/OS-II** examples. The two important functions are `main()` (listing 5-1) and `AppStartTask()` (listing 5-2).

Listing 5-1, `main()`

```
void main (void)
{
    INT8U  err;

    BSP_IntDisAll();                               (1)

    OSInit();                                       (2)

    OSTaskCreateExt(AppStartTask,                  (3)
                    (void *)0,
                    (OS_STK *)&AppStartTaskStk[TASK_STK_SIZE-1],
                    TASK_START_PRIO,
                    TASK_START_PRIO,
                    (OS_STK *)&AppStartTaskStk[0],
                    TASK_STK_SIZE,
                    (void *)0,
                    OS_TASK_OPT_STK_CHK | OS_TASK_OPT_STK_CLR);

    #if OS_TASK_NAME_SIZE > 11
        OSTaskNameSet(TASK_START_PRIO, "Start Task", &err);   (4)
    #endif

    OSStart();                                     (5)
}
```

- L5-1(1) A BSP function called `BSP_IntDisAll()` is called to disable ALL interrupts. You would typically prevent the interrupt controller from issuing interrupts until your application is ready to service them.
- L5-1(2) As with all **µC/OS-II** based applications, you need to initialize **µC/OS-II** by calling `OSInit()`.
- L5-1(3) You need to create at least one task. In this case, we created the task using the extended task create call. This allow **µC/OS-II** to have more information about your task.
- L5-1(4) We can now give a name for our task.
- L5-1(5) In order to start multitasking, you need to call `OSStart()`. Note that `OSStart()` will not return from this call.

Listing 5-2, AppStartTask()

```
static void AppStartTask (void *p_arg)
{
    (void)p_arg;

    BSP_Init();                                     (1)

    #if OS_TASK_STAT_EN > 0
        OSStatInit();                             (2)
    #endif

    #if (uC_PROBE_OS_PLUGIN > 0) || (uC_PROBE_COM_MODULE > 0)
        AppProbeInit();
    #endif

    AppTaskCreate();                               (3)

    while (TRUE) {                                 (4)
        for (i = 0; i < 4; i++) {
            for (j = 1; j <= 8; j++) {
                LED_On(j);
                OSTimeDlyHMSM(0, 0, 0, 25);        (5)
                LED_Off(j);
            }

            for (j = 7; j >= 2; j--) {
                LED_On(j);
                OSTimeDlyHMSM(0, 0, 0, 25);
                LED_Off(j);
            }
        }

        for (i = 0; i < 4; i++) {
            LED_On(0);
            OSTimeDlyHMSM(0, 0, 0, 25);
            LED_Off(0);
            OSTimeDlyHMSM(0, 0, 0, 25);
        }
    }
}
```

- L5-2(1) If you decided to implement a BSP (see section 6, Board Support Package) for your target board, you would initialize it here.
- L5-2(2) If you enabled the statistic task by setting OS_TASK_STAT_EN in OS_CFG.H to 1) then, you need to call it here. Please note that you need to make sure that you initialized and enabled the µC/OS-II clock tick because OSStatInit() assumes the presence of clock ticks. In other words, if the tick ISR is not active when you call OSStatInit(), your application will end up in µC/OS-II's idle task and not be able to run any other tasks.
- L5-2(3) At this point, you can create additional tasks. We decided to place all our task initialization in one function called AppTaskCreate() but, you are certainly welcome to use a different technique.
- L5-2(4) You can now perform whatever additional function you want for this task. We decided to toggle an LED by calling a BSP function called LED_Toggle(). It is in fact these nested loops that perform the LED sweep functionality provided in many of our example applications.
- L5-2(5) Each of your tasks **MUST** invoke one of the µC/OS-II functions that will wait for an event to occur. We decided to use OSTimeDlyHMSM() which suspends the task for a specified amount of time.

5.02 INCLUDES.H

INCLUDES.H is a *master* include file and is found at the top of all .C files. INCLUDES.H allows every .C file in your project to be written without concern about which header file is actually needed. The only drawbacks to having a master include file are that INCLUDES.H may include header files that are not pertinent to the actual .C file being compiled and the compilation process may take longer. These inconveniences are offset by code portability. You can edit INCLUDES.H to add your own header files, but your header files should be added at the end of the list. Listing 5-3 shows the typical contents of INCLUDES.H. Of course, you can add your own header files as needed.

Listing 5-3, INCLUDES.H

```
#ifndef      INCLUDES_H
#define      INCLUDES_H

#include     <stdio.h>
#include     <string.h>
#include     <ctype.h>
#include     <stdlib.h>

#include     <p33FJ256GP710.h>    /* Header file name varies with tool-chain */

#include     <cpu.h>
#include     <ucos_ii.h>

#include     <bsp.h>

#include     <lib_def.h>
#include     <lib_str.h>
#include     <lib_mem.h>

#if (uC_PROBE_OS_PLUGIN > 0)
#include     <os_probe.h>
#endif

#if (uC_PROBE_COM_MODULE > 0)
#include     <probe_com.h>

#if (PROBE_COM_METHOD_RS232 > 0)
#include     <probe_rs232.h>
#endif
#endif

#endif      /* End of File */
```

5.03 OS_CFG.H

Every **µC/OS-II** requires that you configure the RTOS for your own application. The configuration of **µC/OS-II** allows to specify how many tasks your application will have, how many semaphores (if any), how many message queues (if any), etc. Configuring **µC/OS-II** allows **µC/OS-II**'s footprint to be only as big as it needs to be.

6.00 BSP (Board Support Package)

It is often convenient to create a Board Support Package (BSP) for your target hardware. A BSP could allow you to encapsulate the following functionality:

- Timer initialization (OS Ticker and View)
- PLL Initialization
- ISR Handlers
- LED control functions
- Reading switches
- Setting up communication channels
- Etc.

A BSP consist of 2 files: `BSP.C` and `BSP.H`.

For example, because a number of evaluation boards are equipped with LEDs, we decided to create LED control functions as follows:

```
void LED_Init(void);
void LED_On(INT8U led);
void LED_Off(INT8U led);
void LED_Toggle(INT8U led);
```

In this case, LEDs are referenced 'logically' instead of physically. When you write the BSP, you determine which LED is LED #1, which is LED #2, etc. When you want to turn on LED #1, you simply call `LED_On(1)`. If you want to toggle LED #2, you simply call `LED_Toggle(2)`. In fact, you can (and should) associate names to your LEDs using `#defines`. You could thus specify `LED_Off(LED_PM)`. Where `LED_PM` 'could' be defined as LED #2.

Each BSP should contain a BSP initialization function. We called ours `BSP_Init()` and should be called by your application code.

We decided to encapsulate the **µC/OS-II** clock tick ISR handler and its initialization function in the BSP because they ideally belong in your application code and not as part of **µC/OS-II**. Doing this makes it easier to adapt the **µC/OS-II** port to different target hardware since you could simply change the BSP to select whichever timer or interrupt source for the clock tick that your application requires. The clock tick ISR is in `BSP_A.S` which in turn calls the `OS_Tick_ISR_Handler()` that is found in `BSP.C`.

7.00 Conclusion

This application note presented a 'generic' port for the dsPIC33 processor. Of course, if you use **μC/OS-II** and use the port on actual hardware, you will need to initialize and properly handle hardware interrupts.

Licensing

If you intend to use **µC/OS-II** in a commercial product, remember that you need to contact **Micrium** to properly license its use in your product. The use of **µC/OS-II** in commercial applications is **NOT-FREE**. Your honesty is greatly appreciated.
