

## PGA11x Zero-Drift Programmable Gain Amplifier With Mux

### 1 Features

- Rail-to-Rail Input and Output
- Offset: 25  $\mu\text{V}$  (Typical), 100  $\mu\text{V}$  (Maximum)
- Zero Drift: 0.35  $\mu\text{V}/^\circ\text{C}$  (Typical), 1.2  $\mu\text{V}/^\circ\text{C}$  (Maximum)
- Low Noise: 12  $\text{nV}/\sqrt{\text{Hz}}$
- Input Offset Current:  $\pm 5$  nA Maximum (25 $^\circ\text{C}$ )
- Gain Error: 0.1% Maximum ( $G \leq 32$ ), 0.3% Maximum ( $G > 32$ )
- Binary Gains: 1, 2, 4, 8, 16, 32, 64, 128 (PGA112, PGA116)
- Scope Gains: 1, 2, 5, 10, 20, 50, 100, 200 (PGA113, PGA117)
- Gain Switching Time: 200 ns
- 2 Channel MUX: PGA112, PGA113  
10 Channel MUX: PGA116, PGA117
- Four Internal Calibration Channels
- Amplifier Optimized for Driving CDAC ADCs
- Output Swing: 50 mV to Supply Rails
- $\text{AV}_{\text{DD}}$  and  $\text{DV}_{\text{DD}}$  for Mixed Voltage Systems
- $\text{I}_{\text{Q}} = 1.1$  mA (Typical)
- Software and Hardware Shutdown:  $\text{I}_{\text{Q}} \leq 4$   $\mu\text{A}$  (Typical)
- Temperature Range:  $-40^\circ\text{C}$  to  $125^\circ\text{C}$
- SPI™ Interface (10 MHz) With Daisy-Chain Capability

### 2 Applications

- Remote e-Meter Reading
- Automatic Gain Control
- Portable Data Acquisition
- PC-Based Signal Acquisition Systems
- Test and Measurement
- Programmable Logic Controllers
- Battery-Powered Instruments
- Handheld Test Equipment

### 3 Description

The PGA112 and PGA113 devices (binary and scope gains) offer two analog inputs, a three-pin SPI interface, and software shutdown in a 10-pin, VSSOP package. The PGA116 and PGA117 (binary and scope gains) offer 10 analog inputs, a SPI interface with daisy-chain capability, and hardware and software shutdown in a 20-pin TSSOP package.

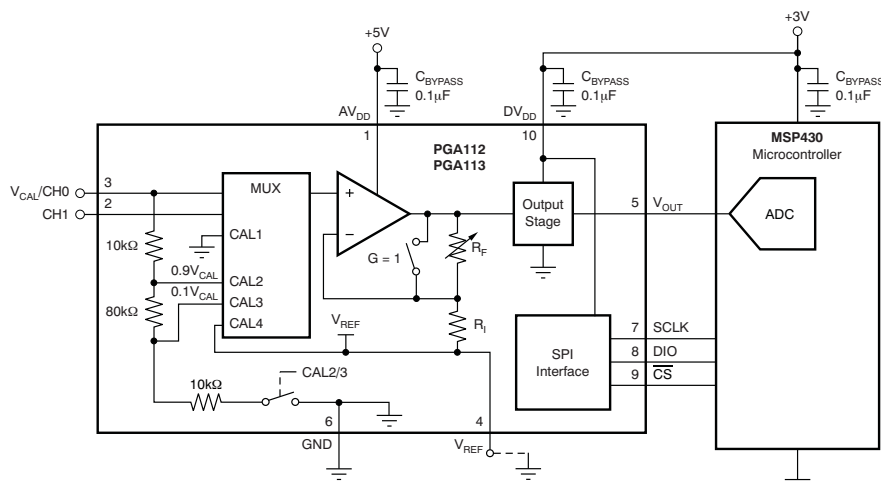

All versions provide internal calibration channels for system-level calibration. The channels are tied to GND,  $0.9 V_{\text{CAL}}$ ,  $0.1 V_{\text{CAL}}$ , and  $V_{\text{REF}}$ , respectively.  $V_{\text{CAL}}$ , an external voltage connected to Channel 0, is used as the system calibration reference. Binary gains are: 1, 2, 4, 8, 16, 32, 64, and 128; scope gains are: 1, 2, 5, 10, 20, 50, 100, and 200.

## 6 Pin Configuration and Functions

**Pin Functions: PGA112, PGA113**

PIN		I/O	DESCRIPTION
NO.	NAME		
1	AV <sub>DD</sub>	I	Analog supply voltage (2.2 V to 5.5 V)
2	CH1	I	Input MUX channel 1
3	V <sub>CAL</sub> /CH0	I	Input MUX channel 0 and V <sub>CAL</sub> input. For system calibration purposes, connect this pin to a low-impedance external reference voltage to use internal calibration channels. The four internal calibration channels are connected to GND, 0.9 V <sub>CAL</sub> , 0.1 V <sub>CAL</sub> , and V <sub>REF</sub> , respectively. V <sub>CAL</sub> is loaded with 100 kΩ (typical) when internal calibration channels CAL2 or CAL3 are selected. Otherwise, V <sub>CAL</sub> /CH0 appears as high impedance.
4	V <sub>REF</sub>	I	Reference input pin. Connect external reference for V <sub>OUT</sub> offset shift or to midsupply for midsupply referenced systems. V <sub>REF</sub> must be connected to a low-impedance reference capable of sourcing and sinking at least 2 mA or V <sub>REF</sub> must be connected to GND.
5	V <sub>OUT</sub>	O	Analog voltage output. When AV <sub>DD</sub> < DV <sub>DD</sub> , V <sub>OUT</sub> is clamped to AV <sub>DD</sub> + 300 mV.
6	GND	—	Ground pin
7	SCLK	I	Clock input for SPI serial interface
8	DIO	I	Data input/output for SPI serial interface. DIO contains a weak, 10-μA internal pull-down current source.
9	$\overline{\text{CS}}$	I	Chip select line for SPI serial interface
10	DV <sub>DD</sub>	I	Digital and op amp output stage supply voltage (2.2 V to 5.5 V). Useful in multi-supply systems to prevent overvoltage and lockup condition on an analog-to-digital (ADC) input (for example, a microcontroller with an ADC running on 3 V and the PGA powered from 5 V). Digital I/O levels to be relative to DV <sub>DD</sub> . DV <sub>DD</sub> should be bypassed with a 0.1-μF ceramic capacitor, and DV <sub>DD</sub> must supply the current for the digital portion of the PGA as well as the load current for the op amp output stage.

**Pin Functions: PGA116, PGA117**

PIN		I/O	DESCRIPTION
NO.	NAME		
1	AV <sub>DD</sub>	I	Analog supply voltage (2.2 V to 5.5 V)
2	CH5	I	Input MUX channel 5
3	CH4	I	Input MUX channel 4
4	CH3	I	Input MUX channel 3
5	CH2	I	Input MUX channel 2
6	CH1	I	Input MUX channel 1
7	V <sub>CAL</sub> /CH0	I	Input MUX channel 0 and V <sub>CAL</sub> input. For system calibration purposes, connect this pin to a low-impedance external reference voltage to use internal calibration channels. The four internal calibration channels are connected to GND, 0.9 V <sub>CAL</sub> , 0.1 V <sub>CAL</sub> , and V <sub>REF</sub> , respectively. V <sub>CAL</sub> is loaded with 100 kΩ (typical) when internal calibration channels CAL2 or CAL3 are selected. Otherwise, V <sub>CAL</sub> /CH0 appears as high impedance.
8	V <sub>REF</sub>	I	Reference input pin. Connect external reference for V <sub>OUT</sub> offset shift or to midsupply for midsupply referenced systems. V <sub>REF</sub> must be connected to a low-impedance reference capable of sourcing and sinking at least 2 mA or to GND.
9	V <sub>OUT</sub>	O	Analog voltage output. When AV <sub>DD</sub> < DV <sub>DD</sub> , V <sub>OUT</sub> is clamped to AV <sub>DD</sub> + 300 mV.
10	CH7	I	Input MUX channel 7
11	CH8	I	Input MUX channel 8
12	CH9	I	Input MUX channel 9
13	ENABLE	I	Hardware enable pin. Logic low puts the part into Shutdown mode (I <sub>Q</sub> < 1 μA).
14	GND	—	Ground pin
15	SCLK	I	Clock input for SPI serial interface
16	DIN	I	Data input for SPI serial interface. DIN contains a weak, 10-μA internal pulldown current source to allow for ease of daisy-chain configurations.
17	DOUT	O	Data output for SPI serial interface. DOUT goes to high-Z state when $\overline{CS}$ goes high for standard SPI interface.
18	$\overline{CS}$	I	Chip select line for SPI serial interface
19	DV <sub>DD</sub>	I	Digital and op amp output stage supply voltage (2.2 V to 5.5 V). Useful in multi-supply systems to prevent overvoltage and lockup condition on an ADC input (for example, a microcontroller with an ADC running on 3 V and the PGA powered from 5 V). Digital I/O levels to be relative to DV <sub>DD</sub> . DV <sub>DD</sub> should be bypassed with a 0.1-μF ceramic capacitor, and DV <sub>DD</sub> must supply the current for the digital portion of the PGA as well as the load current for the op amp output stage.
20	CH6	I	Input MUX channel 6

## 7 Specifications

### 7.1 Absolute Maximum Ratings

Over operating free-air temperature range, unless otherwise noted.<sup>(1)</sup>

	MIN	MAX	UNIT
Supply voltage		7	V
Signal input terminals, voltage <sup>(2)</sup>	GND – 0.5	AV <sub>DD</sub> + 0.5	V
Signal input terminals, current <sup>(2)</sup>		±10	mA
Output short circuit		Continuous	
Operating temperature	–40	125	°C
Junction temperature		150	°C
Storage temperature	–65	150	°C

- (1) Stresses above these ratings may cause permanent damage. Exposure to absolute maximum conditions for extended periods may degrade device reliability. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those specified is not implied.
- (2) Input terminals are diode-clamped to the power-supply rails. Input signals that can swing more than 0.5 V beyond the supply rails should be current-limited to 10 mA or less.

### 7.2 ESD Ratings

		VALUE	UNIT
V <sub>(ESD)</sub> Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 <sup>(1)</sup>	±3000	V
	Charged-device model (CDM), per JEDEC specification JESD22-C101 <sup>(2)</sup>	±1000	
	Machine Model (MM)	±300	

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
- (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

### 7.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

	MIN	NOM	MAX	UNIT
AV <sub>DD</sub>	2.2	5	5.5	V
DV <sub>DD</sub>	2.2	5	5.5	V
Operating temperature	–40	25	125	°C

### 7.4 Thermal Information

THERMAL METRIC <sup>(1)</sup>		PGA112, PGA113	PGA116, PGA117	UNIT
		DGS (VSSOP)	PW (TSSOP)	
		10 PINS	20 PINS	
R <sub>θJA</sub>	Junction-to-ambient thermal resistance	98.3	100.3	°C/W
R <sub>θJC(top)</sub>	Junction-to-case (top) thermal resistance	57	36.9	°C/W
R <sub>θJB</sub>	Junction-to-board thermal resistance	51.2	50.6	°C/W
ψ <sub>JT</sub>	Junction-to-top characterization parameter	1.3	2.6	°C/W
ψ <sub>JB</sub>	Junction-to-board characterization parameter	36.9	50.2	°C/W
R <sub>θJC(bot)</sub>	Junction-to-case (bottom) thermal resistance	4.8	N/A	°C/W

- (1) Gain error is a function of the input voltage. Gain error outside of the range ( $\text{GND} + 85\text{ mV} \leq V_{OUT} \leq DV_{DD} - 85\text{ mV}$ ) increases to 0.5% (typical).
- (2) Input voltages beyond this range must be current-limited to  $< |10\text{ mA}|$  through the input protection diodes on each channel to prevent permanent destruction of the device.
- (3) See [Figure 55](#).
- (4) Total  $V_{OUT}$  error must be computed using input offset voltage error multiplied by gain. Includes op amp  $G = 1$  error.

## 8 Detailed Description

### 8.1 Overview

The PGA112 and PGA113 devices (binary and scope gains) offer two analog inputs, a three-pin SPI interface, and software shutdown in an 10-pin VSSOP package. The PGA116 and PGA117 (binary and scope gains) offer 10 analog inputs, and hardware and software shutdown in a 20-pin TSSOP package.

All versions provide internal calibration channels for system-level calibration. The channels are tied to GND,  $0.9V_{CAL}$ ,  $0.1V_{CAL}$ , and  $V_{REF}$ , respectively.  $V_{CAL}$ , an external voltage connected to Channel 0, is used as the system calibration reference. Binary gains are: 1, 2, 4, 8, 16, 32, 64, and 128; scope gains are: 1, 2, 5, 10, 20, 50, 100, and 200.

The PGA uses a SPI interface with daisy-chain capability, a standard serial peripheral interface (SPI). Both SPI Mode 0,0 and Mode 1,1 are supported, as shown in [Figure 56](#) and described in [Table 2](#).

### 8.2 Functional Block Diagram

### 8.3 Feature Description

Featuring low offset, low offset drift and low noise, the PGA11x series provides a flexible analog building block for a variety of applications. The PGA112 and PGA116 offer binary gains of 1, 2, 4, 8, 16, 32, 64, 128 and a 2 channel MUX while the PGA113 and PGA117 offer scope gains of 1, 2, 5, 10, 20, 50, 100, 200 and a 10 channel MUX.

### 8.4 Device Functional Modes

The PGA112 and PGA113 devices have a software shutdown mode, and the PGA116 and PGA117 devices offer both a hardware and software shutdown mode, see [Shutdown and Power-On-Reset \(POR\)](#) for additional information. The PGA uses a standard serial peripheral interface (SPI). Both SPI Mode 0,0 and Mode 1,1 are supported. More information regarding serial communications, including daisy chaining can be found in [Serial Interface Information](#).

8.6.1 Serial Digital Interface: SPI Modes

The PGA uses a standard serial peripheral interface (SPI). Both SPI Mode 0,0 and Mode 1,1 are supported, as shown in Figure 56 and described in Table 2.

If there are not even-numbered increments of 16 clocks (that is, 16, 32, 64, and so forth) between  $\overline{CS}$  going low (falling edge) and  $\overline{CS}$  going high (rising edge), the device takes no action. This condition provides reliable serial communication. Furthermore, this condition also provides a way to quickly reset the SPI interface to a known starting condition for data synchronization. Transmitted data are latched internally on the rising edge of  $\overline{CS}$ .

On the PGA116 and PGA117 devices,  $\overline{CS}$ , DIN, and SCLK are Schmitt-triggered CMOS logic inputs. DIN has a weak internal pulldown to support daisy-chain communications on the PGA116 and PGA117 devices. DOUT is a CMOS logic output. When  $\overline{CS}$  is high, the state of DOUT is high-impedance. When  $\overline{CS}$  is low, DOUT is driven as illustrated in Figure 57.

Figure 57. Digital I/O Structure—PGA116 and PGA117

On the PGA112 and PGA113 devices, there are digital output and digital input gates both internally connected to the DIO pin. DIN is an input-only gate and DOUT is a digital output that can give a 3-state output. The DIO pin has a weak 10-µA pulldown current source to prevent the pin from floating in systems with a high-impedance SPI DOUT line. When  $\overline{CS}$  is high, the state of the internal DOUT gate is high-impedance. When  $\overline{CS}$  is low, the state of DIO depends on the previous valid SPI communication; either DIO becomes an output to clock out data or it remains an input to receive data. This structure is shown in Figure 58.

Figure 58. Digital I/O Structure—PGA112 and PGA113

### 8.6.2 Serial Digital Interface: SPI Daisy-Chain Communications

To reduce the number of I/O port pins used on a microcontroller, the PGA116 and PGA117 support SPI daisy-chain communications with full read and write capability. A two-device daisy-chain configuration is shown in [Figure 59](#), although any number of devices can be daisy-chained. The SPI daisy-chain communication uses a common SCLK and  $\overline{\text{CS}}$  line for all devices in the daisy chain, rather than each device requiring a separate  $\overline{\text{CS}}$  line. The daisy-chain mode of communication routes data serially through each device in the chain by using its respective DIN and DOUT pins as shown. Special commands are used (see [Table 4](#)) to ensure that data are written or read in the proper sequence. There is a special daisy-chain NOP command (No Operation) which, when presented to the desired device in the daisy-chain, causes no changes in that respective device. Detailed timing diagrams for daisy-chain operation are shown in [Figure 63](#) through [Figure 65](#).

Figure 59. Daisy-Chain Read and Write Configuration

The PGA112 and PGA113 devices can be used as the last device in a daisy-chain as shown in [Figure 60](#) if *write-only* communication is acceptable, because the PGA112 and PGA113 devices have no separate DOUT pin to connect back to the microcontroller DIN pin to read back data in this configuration.

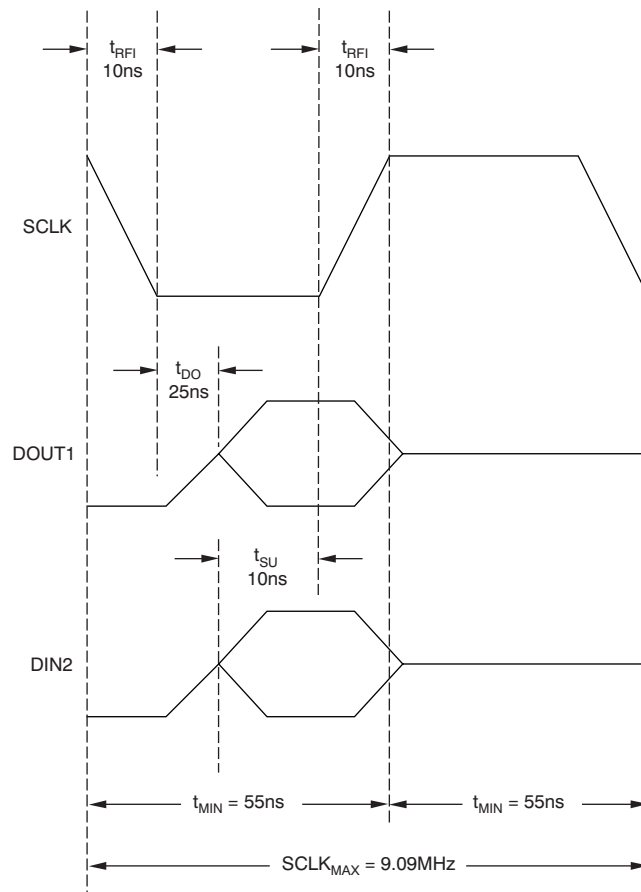

Figure 60. Daisy-Chain Write-Only Configuration

The maximum SCLK frequency that can be used in daisy-chain operation is directly related to SCLK rise and fall times, DIN setup time, and DOUT propagation delay. Any number of two or more devices have the same limitations because it is the timing considerations between adjacent devices that limit the clock speed.

[Figure 61](#) analyzes the maximum SCLK frequency for daisy-chain mode based on the circuit of [Figure 59](#). A clock rise and fall time of 10 ns is assumed to allow for extra bus capacitance that could occur as a result of multiple devices in the daisy-chain.

## 9 Applications and Implementation

### NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

### 9.1 Application Information

The PGA11x family of devices are single-ended input, single-supply, programmable gain amplifiers (PGAs) with an input multiplexer. Multiplexer channel selection and gain selection are done through a standard SPI interface. The PGA112 and PGA113 have a two-channel input MUX and the PGA116 and PGA117 devices have a 10-channel input MUX. The PGA112 and PGA116 devices provide binary gain selections (1, 2, 4, 8, 16, 32, 64, 128) and the PGA113 and PGA117 devices provide scope gain selections (1, 2, 5, 10, 20, 50, 100, 200). All models use a split-supply architecture with an analog supply,  $AV_{DD}$ , and a digital supply,  $DV_{DD}$ . This split-supply architecture allows for ease of interface to analog-to-digital converters (ADCs) and microcontrollers in mixed-supply voltage systems, such as where the analog supply is 5 V and the digital supply is 3 V. Four internal calibration channels are provided for system-level calibration. The channels are tied to GND,  $0.9 V_{CAL}$ ,  $0.1 V_{CAL}$ , and  $V_{REF}$ , respectively.  $V_{CAL}$ , an external voltage connected to  $V_{CAL}/CH0$ , acts as the system calibration reference. If  $V_{CAL}$  is the system ADC reference, then gain and offset calibration on the ADC are easily accomplished through the PGA11x devices using only one MUX input. If calibration is not used, then  $V_{CAL}/CH0$  can be used as a standard MUX input. All four versions provide a  $V_{REF}$  pin that can be tied to ground or, for ease of scaling, to midsupply in single-supply systems where midsupply is used as a virtual ground. The PGA112 and PGA113 devices offer a software-controlled shutdown feature for low standby power. The PGA116 and PGA117 devices offer both hardware- and software-controlled shutdown for low standby power. The PGA112 and PGA113 devices have a 3-wire SPI digital interface; the PGA116 and PGA117 devices have a four-wire SPI digital interface. The PGA116 and PGA117 devices also have daisy-chain capability.

#### 9.1.1 Op Amp: Input Stage

The PGA op amp is a rail-to-rail input and output (RRIO) single-supply op amp. The input topology uses two separate input stages in parallel to achieve rail-to-rail input. As [Figure 66](#) shows, there is a PMOS transistor on each input for operation down to ground; there is also an NMOS transistor on each input in parallel for operation to the positive supply rail. When the common-mode input voltage (that is, the single-ended input, because this PGA is configured internally for noninverting gain) crosses a level that is typically about 1.5 V less than the positive supply, there is a transition between the NMOS and PMOS transistors. The result of this transition appears as a small input offset voltage transition that is reflected to the output by the selected PGA gain. This transition may be either increasing or decreasing, and differs from part to part as described in [Figure 67](#) and [Figure 68](#). These figures illustrate possible differences in input offset voltage between two different devices when used with  $AV_{DD} = 5$  V. Because the exact transition region varies from device to device, the [Electrical Characteristics:  \$V\_S = AV\_{DD} = DV\_{DD} = 5\$  V](#) table specifies an input offset voltage above and below this input transition region.

9.1.2 Op Amp: General Gain Equations

Figure 69 shows the basic configuration for using the PGA as a gain block.  $V_{OUT} / V_{IN}$  is the selected noninverting gain, depending on the model selected, for either binary or scope gains.

$$V_{OUT} = G \times V_{IN}$$

where

- G = 1, 2, 4, 8, 16, 32, 64, and 128 (binary gains)
- G = 1, 2, 5, 10, 20, 50, 100, and 200 (scope gains) (1)

Figure 70 shows the PGA configuration and gain equations for  $V_{REF} = AV_{DD}/2$ .  $V_{OUT0}$  is  $V_{OUT}$  when CH0 is selected and  $V_{OUT1}$  is  $V_{OUT}$  when CH1 is selected. Notice the  $V_{REF}$  pin has no effect for  $G = 1$  because the internal feedback resistor,  $R_F$ , is shorted out. This configuration allows for positive and negative voltage excursions around a midsupply virtual ground.

$$V_{OUT0} = G \times V_{IN0} - AV_{DD}/2 \times (G - 1) \tag{2}$$

When:  $G = 1$

Then:  $V_{OUT0} = G \times V_{IN0}$

$$V_{OUT1} = G \times (V_{IN1} + AV_{DD}/2) - AV_{DD}/2 \times (G - 1)$$

$$V_{OUT1} = G \times V_{IN1} + AV_{DD}/2, \text{ where: } -AV_{DD}/2 < G \times V_{IN1} < +AV_{DD}/2$$

**9.1.3 Op Amp: Frequency Response Versus Gain**

Table 8 documents how small-signal bandwidth and slew rate change correspond to changes in PGA gain.

Full power bandwidth (that is, the highest frequency that a sine wave can pass through the PGA for a given gain) is related to slew rate by Equation 4:

$$SR (V/\mu s) = 2\pi f \times V_{OP} (1 \times 10^{-6})$$

where

- SR = Slew rate in V/ $\mu$ s
- f = Frequency in Hz
- $V_{OP}$  = Output peak voltage in volts

(4)

**9.1.3.1 Example:**

For  $G = 8$ , then  $SR = 10.6 V/\mu s$  (slew rate rise is minimum slew rate).

For a 5-V system, choose  $0.1 V < V_{OUT} < 4.9 V$  or  $V_{OUTPP} = 4.8 V$  or  $V_{OUTP} = 2.4 V$ .

$$SR (V/\mu s) = 2\pi f \times V_{OP} (1 \times 10^{-6}).$$

$$10.6 = 2\pi f (2.4) (1 \times 10^{-6}) \rightarrow f = 702.9 \text{ kHz}$$

This example shows that a  $G = 8$  configuration can produce a 4.8- $V_{PP}$  sine wave with frequency up to 702.9 kHz. This computation only shows the theoretical upper limit of frequency for this example, but does not indicate the distortion of the sine wave. The acceptable distortion depends on the specific application. As a general guideline, maintain two to three times the calculated slew rate to minimize distortion on the sine wave. For this example, the application should only use  $G = 8$ , 4.8  $V_{PP}$ , up to a frequency range of 234 kHz to 351 kHz, depending upon the acceptable distortion. For a given gain and slew rate requirement, check for adequate small-signal bandwidth (typical -3-dB frequency) to assure that the frequency of the signal can be passed without attenuation.

**9.1.4 Analog MUX**

The analog input MUX provides two input channels for the PGA112 and PGA113 devices and 10 input channels for the PGA116 and PGA117 devices. The MUX switches are designed to be break-before-make and thereby eliminate any concerns about shorting the two input signal sources together.

Four internal MUX CAL channels are included in the analog MUX for ease of system calibration. These CAL channels allow ADC gain and offset errors to be calibrated out. This calibration does not remove the offset and gain errors of the PGA for gains greater than 1, but most systems should see a significant increase in the ADC accuracy. In addition, these CAL channels can be used by the ADC to read the minimum and maximum possible voltages from the PGA. With these minimum and maximum levels known, the system architecture can be designed to indicate an out-of-range condition on the measured analog input signals if these levels are ever measured.

To use the CAL channels,  $V_{CAL}/CH0$  must be permanently connected to the system ADC reference. There is a typical 100-k $\Omega$  load from  $V_{CAL}/CH0$  to ground. Table 9 illustrates how to use the CAL channels with  $V_{REF} =$  ground. Table 10 describes how to use the CAL channels with  $V_{REF} = AV_{DD}/2$ . The  $V_{REF}$  pin must be connected to a source that is low-impedance for both DC and AC to maintain gain and nonlinearity accuracy. Worst-case current demand on the  $V_{REF}$  pin occurs when  $G = 1$  because there is a 3.25-k $\Omega$  resistor between  $V_{OUT}$  and  $V_{REF}$ . For a 5-V system with  $AV_{DD}/2 = 2.5$  V, the  $V_{REF}$  pin buffer must source and sink  $2.5$  V/3.25 k $\Omega = 0.7$  mA minimum for a  $V_{OUT}$  that can swing from ground to 5 V.

### 9.1.5 System Calibration Using The PGA

Analog-to-digital converters (ADCs) contain two major errors that can be easily removed by calibration at a system level. These errors are gain error and offset error, as shown in [Figure 73](#). [Figure 73](#) shows a typical transfer function for a 12-bit ADC. The analog input is on the x-axis with a range from 0 V to ( $V_{REF\_ADC} - 1\text{LSB}$ ), where  $V_{REF\_ADC}$  is the ADC reference voltage. The y-axis is the hexadecimal equivalent of the digital codes that result from ADC conversions. The dotted red line represents an ideal transfer function with  $0000h$  representing 0 V analog input and  $0FFFh$  representing an analog input of ( $V_{REF\_ADC} - 1\text{LSB}$ ). The solid blue line illustrates the offset error. Although the solid blue line includes both offset error and gain error, at an analog input of 0 V the offset error voltage,  $V_{Z\_ACTUAL}$ , can be measured. The dashed black line represents the transfer function with gain error. The dashed black line is equivalent to the solid blue line without the offset error, and can be measured and computed using  $V_{Z\_ACTUAL}$  and  $V_{Z\_IDEAL}$ . The difference between the dashed black line and the dotted red line is the gain error. Gain and offset error can be computed by taking zero input and full-scale input readings. Using these error calculations, compute a calibrated ADC reading to remove the ADC gain and offset error.

**Figure 73. ADC Offset and Gain Error**

In practice, the zero input (0 V) or full-scale input ( $V_{REF\_ADC} - 1LSB$ ) of ADCs cannot always be measured because of internal offset error and gain error. However, if measurements are made very close to the full-scale input and the zero input, both zero and full-scale can be calibrated very accurately with the assumption of linearity from the calibration points to the desired end points of the ADC ideal transfer function. For the zero calibration, choose  $10\%V_{REF\_ADC}$ ; this value should be above the internal offset error and sufficiently out of the noise floor range of the ADC. For the gain calibration, choose  $90\%V_{REF\_ADC}$ ; this value should be less than the internal gain error and sufficiently below the tolerance of  $V_{REF}$ . These key points can be summarized in this way:

For zero calibration:

- The ADC cannot read the ideal zero because of offset error
- Must be far enough above ground to be above noise floor and ADC offset error
- Therefore, choose  $10\%V_{REF\_ADC}$  for zero calibration

For gain calibration:

- The ADC cannot read the ideal full-scale because of gain error
- Must be far enough below full-scale to be below the  $V_{REF}$  tolerance and ADC gain error
- Therefore, choose  $90\%V_{REF\_ADC}$  for gain calibration

The 12-bit ADC example in [Figure 74](#) illustrates the technique for calibrating an ADC using a  $10\%V_{REF\_ADC}$  and  $90\%V_{REF\_ADC}$  reading where  $V_{REF\_ADC}$  is the ADC reference voltage. The  $10\%V_{REF}$  reading also contains a gain error because it is not a  $V_{IN} = 0$  calibration point. First, use the  $90\%V_{REF}$  and  $10\%V_{REF}$  points to compute the measured gain error. The measured gain error is then used to remove the gain error from the  $10\%V_{REF}$  reading, giving a measured  $10\%V_{REF}$  number. The measured  $10\%V_{REF}$  number is used to compute the measured offset error.

**Figure 74. 12-Bit Example of ADC Calibration for Gain and Offset Error**

The gain error and offset error in ADC readings can be calibrated by using  $10\%V_{REF\_ADC}$  and  $90\%V_{REF\_ADC}$  calibration points. Because the calibration is ratiometric to  $V_{REF\_ADC}$ , the exact value of  $V_{REF\_ADC}$  does not need to be known in the end application.

Follow these steps to compute a calibrated ADC reading:

1. Take the ADC reading at  $V_{IN} = 90\% \times V_{REF}$  and  $V_{IN} = 10\% \times V_{REF}$ . The ADC readings for  $10\%V_{REF}$  and  $90\%V_{REF}$  are taken.

$$V_{REF90} = 0.9(V_{REF\_ADC}) \quad (5)$$

$$V_{REF10} = 0.1(V_{REF\_ADC}) \quad (6)$$

$$V_{MEAS90} = ADC_{MEASUREMENT} \text{ at } V_{REF90} \quad (7)$$

$$V_{MEAS10} = ADC_{MEASUREMENT} \text{ at } V_{REF10} \quad (8)$$

2. Compute the ADC measured gain. The slope of the curve connecting the measured  $10\%V_{REF}$  and measured  $90\%V_{REF}$  point is computed and compared to the slope between the ideal  $10\%V_{REF}$  and ideal  $90\%V_{REF}$ . This result is the measured gain.

$$G_{MEAS} = \frac{V_{MEAS90} - V_{MEAS10}}{V_{REF90} - V_{REF10}} \quad (9)$$

3. Compute the ADC measured offset. The measured offset is computed by taking the difference between the measured  $10\%V_{REF}$  and the  $(\text{ideal } 10\%V_{REF}) \times (\text{measured gain})$ .

$$O_{MEAS} = V_{MEAS10} - (V_{REF10} \times G_{MEAS}) \quad (10)$$

4. Compute the calibrated ADC readings.

$$V_{AD\_MEAS} = \text{Any } V_{IN} \text{ ADC}_{MEASUREMENT} \quad (11)$$

$$V_{ADC\_CAL} = \frac{V_{AD\_MEAS} - O_{MEAS}}{G_{MEAS}} \quad (12)$$

Any ADC reading can therefore be calibrated by removing the gain error and offset error. The measured offset is subtracted from the ADC reading and then divided by the measured gain to give a corrected reading. If this calibration is performed on a timed basis, relative to the specific application, gain and offset error over temperature are also removed from the ADC reading by calibration.

For example; given:

- 12-Bit ADC
- ADC Gain Error = 6 LSB
- ADC Offset Error = 4 LSB
- ADC Reference ( $V_{REF\_ADC}$ ) = 5 V
- Temperature = 25°C

Table 11 shows the resulting system accuracy.

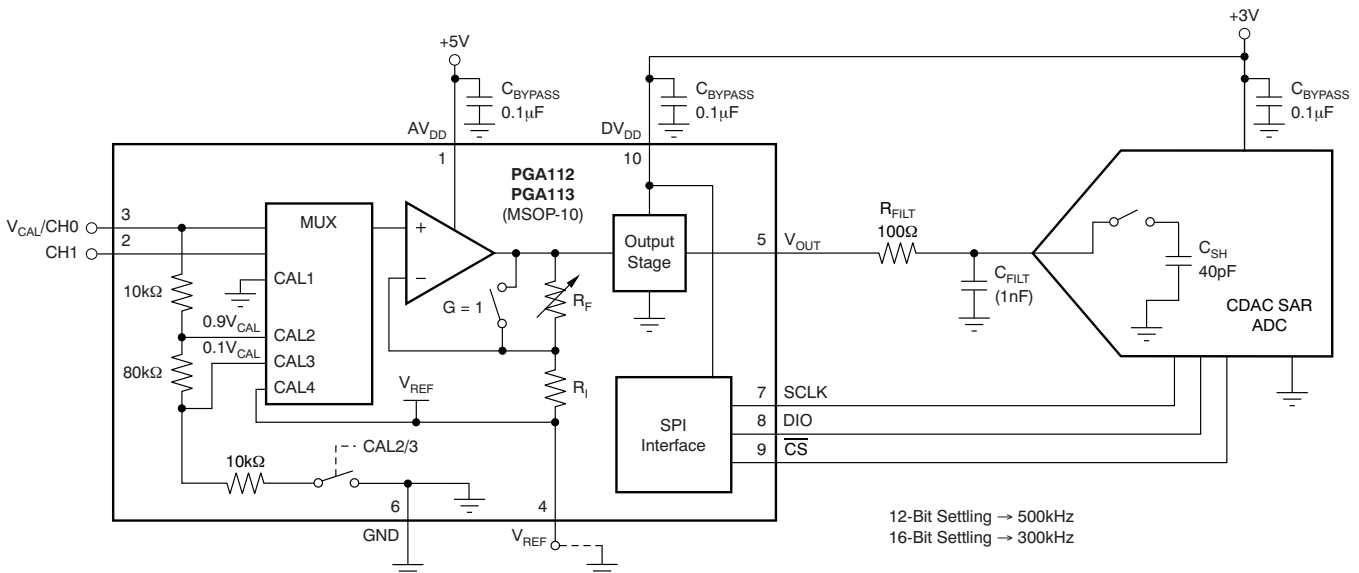

**Table 11. Bits of System Accuracy<sup>(1)</sup> (To 0.5 LSB)**

$V_{IN}$	ADC ACCURACY WITHOUT CALIBRATION	ADC ACCURACY WITH PGA112 CALIBRATION
10% $V_{REF\_ADC}$	8.80 Bits	12.80 Bits
90% $V_{REF\_ADC}$	7.77 Bits	11.06 Bits

(1) Difference in maximum input offset voltage for  $V_{IN} = 10\%V_{REF\_ADC}$  and  $V_{IN} = 90\%V_{REF\_ADC}$  is the reason for different accuracies.

### 9.1.6 Driving and Interfacing to ADCs

CDAC SAR ADCs contain an input sampling capacitor,  $C_{SH}$ , to sample the input signal during a sample period as shown in Figure 75. After the sample period,  $C_{SH}$  is removed from the input signal. Subsequent comparisons of the charge stored on  $C_{SH}$  are performed during the ADC conversion process. To achieve optimal op amp stability, input signal settling, and the demands for charge from the input signal conditioning circuitry, most ADC applications are optimized by the use of a resistor ( $R_{FILT}$ ) and capacitor ( $C_{FILT}$ ) filter placed between the op amp output and ADC input. For the PGA112 and PGA113 devices, or the PGA116 and PGA117 devices, setting  $C_{FILT} = 1$  nF and  $R_{FILT} = 100 \Omega$  yields optimum system performance for sampling converters operating at speeds up to 500 kHz, depending upon the application settling time and accuracy requirements.

**Figure 75. Driving and Interfacing to ADCs**

### 9.1.7 Power Supplies

Figure 76 shows a typical mixed-supply voltage system where the analog supply,  $AV_{DD}$ , is 5 V and the digital supply voltage,  $DV_{DD}$ , is 3 V. The analog output stage of the PGA and the SPI interface digital circuitry are both powered from  $DV_{DD}$ . When considering the power required for  $DV_{DD}$ , use the *Electrical Characteristics:  $V_S = AV_{DD} = DV_{DD} = 5 V$*  table and add any load current anticipated on  $V_{OUT}$ ; this load current must be provided by  $DV_{DD}$ . This split-supply architecture ensures compatible logic levels with the microcontroller. It also ensures that the PGA output cannot run the input for the onboard ADC into an overvoltage condition; this condition could cause device latch-up and system lock-up, and require power-supply sequencing. Each supply pin should be individually bypassed with a 0.1  $\mu F$  ceramic capacitor directly at the device to ground. If there is only one power supply in the system,  $AV_{DD}$  and  $DV_{DD}$  can both be connected to the same supply; however, TI recommends using individual bypass capacitors directly at each respective supply pin to a single point ground.  $V_{OUT}$  is diode-clamped to  $AV_{DD}$  (as shown in Figure 76); therefore, set  $DV_{DD}$  less than or equal to  $AV_{DD} + 0.3 V$ .  $DV_{DD}$  and  $AV_{DD}$  must be within the operating voltage range of 2.2 V to 5.5 V.

At initial power-on, the state of the PGA is  $G = 1$  and Channel 0 active.

#### NOTE

For most applications, set  $AV_{DD} \geq DV_{DD}$  to prevent  $V_{OUT}$  from driving current into  $AV_{DD}$  and raising the voltage level of  $AV_{DD}$

### 9.1.8 Shutdown and Power-On-Reset (POR)

The PGA112 and PGA113 devices have a software shutdown mode, and the PGA116 and PGA117 devices offer both a hardware and software shutdown mode. When the PGA11x is shut down, it goes into a low-power standby mode. The *Electrical Characteristics:  $V_S = AV_{DD} = DV_{DD} = 5 V$*  table details the current draw in shutdown mode with and without the SPI interface being clocked. In shutdown mode,  $R_F$  and  $R_I$  remain connected between  $V_{OUT}$  and  $V_{REF}$ .

When  $DV_{DD}$  is less than 1.6 V, the digital interface is disabled and the channel and gain selections are held to the respective POR states of Gain = 1 and Channel =  $V_{CAL}/CH0$ . When  $DV_{DD}$  is above 1.8 V, the digital interface is enabled and the POR gain and channel states remain unchanged until a valid SPI communication is received.

(1) Scaling is based on 0.02(V<sub>REF\_ADC</sub>) to 0.98(V<sub>REF\_ADC</sub>), using standard 0.1% resistor values.

(2) Assumes symmetrical V<sub>IN</sub> and symmetrical scaling for CH1 input minimum and maximum.

### 9.2.1.2 Detailed Design Procedure

This process assumes a symmetrical  $V_{IN1}$  and that symmetrical scaling is used for CH1 input minimum and maximum values. The following steps give the algorithm to compute resistor values for references not listed in [Table 12](#).

Step 1: Choose the following:

- $V_{REF\_ADC} = 2.5\text{ V}$  (ADC reference voltage)
- $|V_{IN1}| = 5$   
(magnitude of  $V_{IN}$ , assuming scaling is for  $\pm V_{IN1}$ )
- Choose  $R_B$  as a standard resistor value. The input on-channel current multiplied by  $R_B$  should be less than the input offset voltage, such that  $R_B$  is not a major source of inaccuracy.  
 $R_B = 10\text{ k}\Omega$  (select as a starting value for resistors)
- For the most negative  $V_{IN1}$ , choose the percentage (in decimal format) of  $V_{REF\_ADC}$  desired at the ADC input.  
 $k_{VO-} = 0.02$   
(CH1 input =  $k_{VO-} \times V_{REF\_ADC}$  when  $V_{IN1} = -V_{IN1}$ )
- For the most positive  $V_{IN1}$ , choose the percentage (in decimal format) of  $V_{REF\_ADC}$  desired at the ADC input. Because this scaling is based on symmetry,  $k_{VO+}$  must be the same percentage away from  $V_{REF\_ADC}$  at the upper limit as at the lower limit where  $k_{VO-}$  is computed.  
 $k_{VO+} = 1 - k_{VO-}$   
 $k_{VO+} = 1 - 0.02 = 0.98$   
(CH1 input =  $k_{VO+} \times V_{REF\_ADC}$  when  $V_{IN1} = +V_{IN1}$ )

Step 2: Compute the following:

- To simplify analysis, create one constant called  $k_{VO}$ .  
 $k_{VO} = k_{VO+} - k_{VO-}$   
 $0.96 = 0.98 - 0.02$  (13)
- A constant,  $g$ , is created to simplify resistor value computations.

$$g = \frac{k_{VO} \times V_{REF\_ADC}}{2 \times |V_{IN1}| - k_{VO} \times V_{REF\_ADC}}$$

$$0.315789474 = \frac{0.96 \times 2.5}{2 \times 5 - 0.96 \times 2.5}$$
 (14)

- $R_A$  is now selected from the starting value of  $R_B$  and the  $g$  constant.

$$R_A = \frac{2 \times R_B \times g}{1 - g}$$

$$9.23077\text{k}\Omega = \frac{2 \times 10\text{k}\Omega \times 0.315789474}{1 - 0.315789474}$$
 (15)

- $R_X$  can now be computed from the starting value of  $R_B$  and the computed value for  $R_A$ .

$$R_X = \frac{R_B \times R_A}{R_B + R_A}$$

$$4.81\text{k}\Omega = \frac{10\text{k}\Omega \times 9.23077\text{k}\Omega}{10\text{k}\Omega + 9.23077\text{k}\Omega}$$
 (16)

### 9.2.1.3 Application Curve

Figure 80. Voltage (V) vs Time (s)

## 9.2.2 Typical Application: General-Purpose Input Scaling

Figure 81 is an example application that demonstrates the flexibility of the PGA for general-purpose input scaling.  $V_{IN0}$  is a  $\pm 100$ -mV input that is ac-coupled into CH0. The PGA112 and PGA113 are powered from a 5-V supply voltage,  $V_S$ , and configured with the  $V_{REF}$  pin connected to  $V_S/2$  (2.5 V).  $V_{CH0}$  is the  $\pm 100$ -mV input, level-shifted and centered on  $V_S/2$  (2.5 V). A gain of 20 is applied to CH0, and because of the PGA113 configuration, the output voltage at  $V_{OUT}$  is  $\pm 2$  V centered on  $V_S/2$  (2.5 V).

CH1 is set to  $G = 1$ ; through a resistive divider and scalar network, we can read  $\pm 5$  V or 0 V. This setting provides bipolar to single-ended input scaling. Table 12 summarizes the scaling resistor values for  $R_A$ ,  $R_X$ , and  $R_B$  for different ADC Ref voltages.  $V_{REF\_ADC}$  is the reference voltage used for the ADC connected to the PGA112 and PGA113 output. It is assumed the ADC input range is 0 V to  $V_{REF\_ADC}$ . The Table 12 section gives the algorithm to compute resistor values for references not listed in Table 12. As a general guideline,  $R_B$  should be chosen such that the input on-channel current multiplied by  $R_B$  is less than or equal to the input offset voltage. This value ensures that the scaling network contributes no more error than the input offset voltage. Individual applications may require other design trade-offs.

## 10 Power Supply Recommendations

**Power-supply bypass:** Bypass each power-supply pin separately. Use a ceramic capacitor connected directly from the power-supply pin to the ground pin of the IC on the same PCB plane. Vias can then be used to connect to ground and voltage planes. This configuration keeps parasitic inductive paths out of the local bypass for the PGA. Good analog design practice dictates the use of a large value tantalum bypass capacitor on the PCB for each respective voltage.

## 11 Layout

### 11.1 Layout Guidelines

#### 11.1.1 High Gain and Wide Bandwidth Considerations

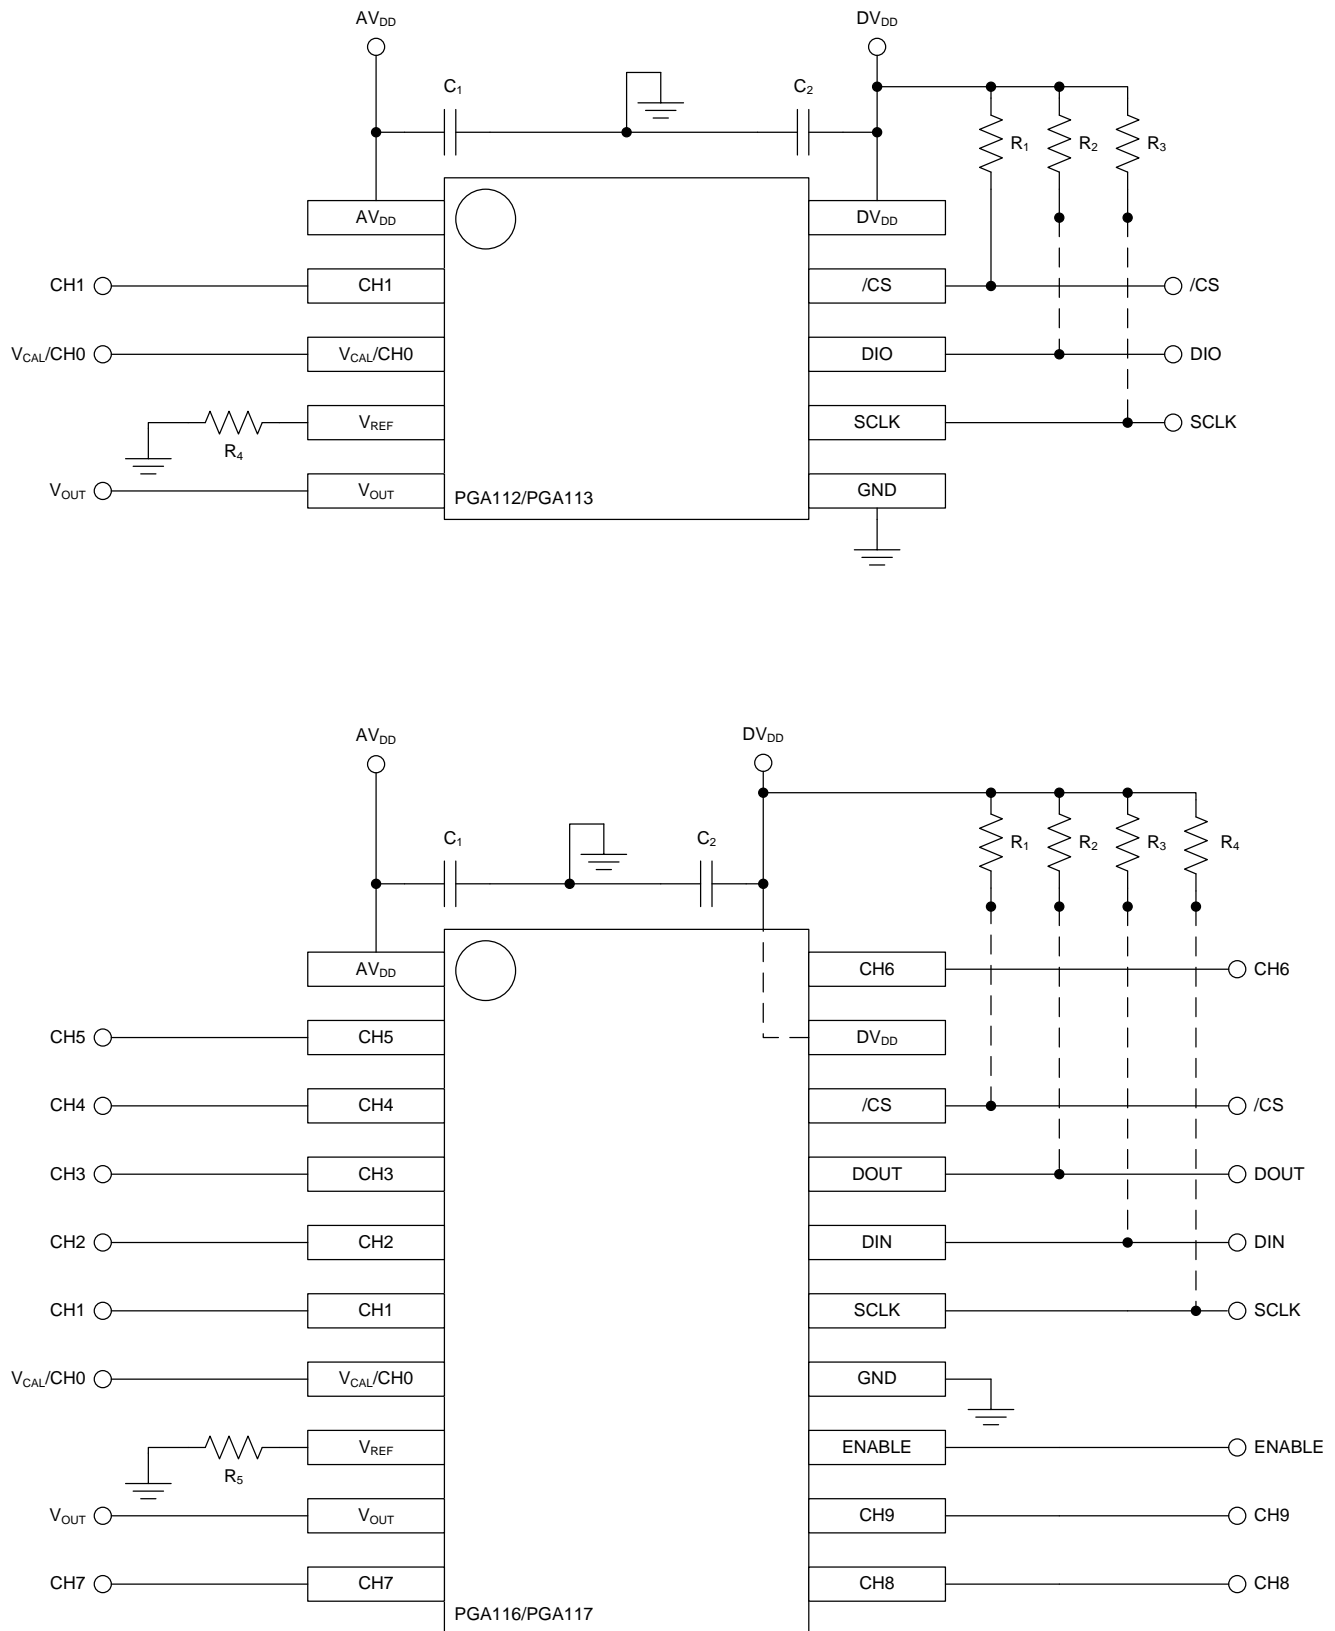

As a result of the combination of wide bandwidth and high gain capability of the PGA112 and PGA113 devices and PGA116 and PGA117 devices, there are several printed-circuit-board (PCB) design and system recommendations to consider for optimum application performance.

1. **Power-supply bypass:** Refer to [Power Supply Recommendations](#).
2. **Signal trace routing:** Keep  $V_{OUT}$  and other low impedance traces away from MUX channel inputs that are high impedance. Poor signal routing can cause positive feedback, unwanted oscillations, or excessive overshoot and ringing on step-changing signals. If the input signals are particularly noisy, separate MUX input channels with guard traces on either side of the signal traces. Connect the guard traces to ground near the PGA and at the signal entry point into the PCB. On multilayer PCBs, ensure that there are no parallel traces near MUX input traces on adjacent layers; capacitive coupling from other layers can be a problem. Use ground planes to isolate MUX input signal traces from signal traces on other layers.

Additionally, group and route the digital signals into the PGA as far away as possible from the analog MUX input signals. Most digital signals are fast rise and fall time signals with low-impedance drive capability that can easily couple into the high-impedance inputs of the input MUX channels. This coupling can create unwanted noise that gains up to  $V_{OUT}$ .

3. **Input MUX channels and source impedance:** Input MUX channels are high-impedance; when combined with high gain, the channels can pick up unwanted noise. Keep the input signal sources low-impedance ( $< 10\text{ k}\Omega$ ). Also, consider bypassing input MUX channels with a ceramic bypass capacitor directly at the MUX input pin. Bypass capacitors greater than 100 pF are recommended. Lower impedances and a bypass capacitor placed directly at the input MUX channels keep crosstalk between channels to a minimum as a result of parasitic capacitive coupling from adjacent PCB traces and pin-to-pin capacitance.

(1) The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

**RoHS Exempt:** TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

**Green:** TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

- (3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.
- (4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.
- (5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.
- (6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.
