

MP2113 1.5A Synchronous Step-Down Converter with Dynamic Voltage Control

The Future of Analog IC Technology

DESCRIPTION

The MP2113 is a fully integrated, internally compensated 1.5MHz fixed frequency PWM step-down converter with dynamic output voltage control. User can select two operation modes, forced PWM and asynchronous mode. Force PWM is ideal for high load operation while asynchronous mode improves efficiency at light load condition. Each mode has independent output level that can be set by the user to optimize the power efficiency. It is ideal for powering portable equipment that runs from a single cell Lithium-Ion (Li+) Battery, with an input range from 2.7V to 6V. The MP2113 can provide 1.5A of load current in forced PWM mode and 50mA in asynchronous mode. Both output voltage can be regulated to as low as 0.6V.

MP2113 integrates the high side switch, a synchronous rectifier for forced PWM mode and a Schottky diode for asynchronous mode operation. With peak current mode control and internal compensation, the MP2113 is stable with ceramic capacitors and small inductors. Fault condition protection includes cycle-by-cycle current limiting and thermal shutdown.

MP2113 is available in the small 8-pin 2mmx3mm QFN package.

FEATURES

- User Selectable Operation Mode: Forced
 PWM and Asynchronous Mode
- User Programmable Output Level for Each Operation Mode
- Dynamic Output Voltage Control
- Up to 1.5A Output Current for Forced PWM Mode, 50mA for Asynchronous Mode
- Internal Power MOSFET Switches and Schottky diode
- Stable with Low ESR Output Ceramic Capacitors
- Up to 95% Efficiency
- 1µA Shutdown Current.
- 1.5MHz Switching Frequency
- Thermal Shutdown
- Cycle-by-Cycle Over Current Protection
- Short circuit protection
- Power-Good Output
- 2.7-6V Input Operation Range
- Output Adjustable from 0.6V to VIN
- Available in 8-pin 2x3mm QFN Package

APPLICATIONS

- DVD+/-RW Drives
- Smart Phones
- PDAs
- Digital Cameras
- Portable Instruments

"MPS" and "The Future of Analog IC Technology" are Registered Trademarks of Monolithic Power Systems, Inc.

PIN FUNCTIONS

Pin #	Name	Description
1	FB	Feedback input.
2	PGOOD	Power-good indicator output. "Open-drain" output indicating that the output is within 10% of the final regulation value. "Low" output indicates output is more than 10% lower than regulation level. PGOOD is pulled down in shutdown. PGOOD comparator shall have 200us deglitch timer to avoid false trigger during transition of operation modes.
3	GND	Ground pin.
4	SW	Switch node to the inductor.
5	IN	Input supply pin.
6	CTRL	Input to control the operation mode. "High" set MP2113 in forced PWM mode, DRN=Low (Pull Down) and "Low" sets MP2113 in low power asynchronous mode, DRN=High. CTRL is pulled up to VIN with 1uA current.
7	EN	Enable input, "High" enables MP2113. EN is pulled to GND with 1Meg internal resistor.
8	DRN	Drain output of an internal switch, controlled by CTRL input. DRN is open circuit when CTRL is "low", and DRN is pulled to ground with on resistance less than 100ohm when CTRL is "high".

OPERATION

The MP2113 is a fixed frequency 1.5MHz current mode 1.5A step-down converter with dynamic voltage control. It has user selectable two operation modes: forced PWM mode for high load and asynchronous mode for light load. The output voltage for each mode can be set independently, through an external resistor divider and a control pin.

MP2113 is optimized for low voltage, Li-Ion battery powered applications where high efficiency and small size are critical.

Forced PWM Mode

The forced PWM mode uses a high side PFET main switch and a low side synchronous rectifier, and always operates in continuous conduction mode. Thus it simplifies the control scheme and eliminates the random spectrum noise due to discontinuous conduction mode.

The steady state duty cycle D for this mode can be calculated as:

$$D = T_{ON} \times f_{OSC} \times 100\% \approx \frac{V_{OUT}}{V_{IN}} \times 100\%$$

Where T_{ON} is the main switch on time and f_{OSC} is the oscillator frequency (1.5MHz typ.).

Current Mode PWM Control

Slope compensated current mode PWM control provides stable switching and cycle-by-cycle current limiting for superior load and line response as well as protection of the internal main switch and synchronous rectifier. The MP2113 switches at a constant frequency (1.5MHz) and modulates the inductor peak current to regulate the output voltage. Specifically, for each cycle the PWM controller forces the inductor peak current to an internal reference level derived from the feedback error voltage. At normal operation, the main switch is turned on at each rise edge of the internal oscillator, and remains on for a certain period of time to ramp up the inductor current. As soon as the inductor current reaches the reference level, the main switch is turned off and immediately the synchronous rectifier will be turned on to provide the inductor current. In forced PWM mode, the synchronous rectifier will stay on until the next oscillator cycle.

Dropout Operation

The MP2113 allows the main switch to remain on for more than one switching cycle to increase the duty cycle when the input voltage is dropping close to the output voltage. When the duty cycle reaches 100%, the main switch is held on continuously to deliver current to the output up to the PFET current limit. In this case, the output voltage becomes the input voltage minus the voltage drop across the main switch and the inductor.

Short Circuit Protection

When the output is shorted to ground, the oscillator frequency is reduced to prevent the inductor current from increasing beyond the PFET current limit. The PFET current limit is also reduced to lower the short circuit current. The frequency and current limit will return to the normal values once the short circuit condition is removed and the feedback voltage approaches 0.6V.

Maximum Load Current

The MP2116 can operate down to 2.7V input voltage; however the maximum load current decreases at lower input due to a large IR drop on the main switch and synchronous rectifier. The slope compensation signal reduces the peak inductor current as a function of the duty cycle to prevent sub-harmonic oscillations at duty cycles greater than 50%. Conversely, the current limit increases as the duty cycle decreases.

Asynchronous Mode Operation

To improve efficiency at light load condition, user can set MP2113 to operate in asynchronous mode. The maximum load current for this mode is designed to be around 50mA.

Mode Switching

User can switch between the two operation modes for MP2113 by toggling the CTRL input pin on the fly. Bring CTRL high will put MP2113 in forced PWM mode and low will put MP2113 in asynchronous mode. CTRL pin can also be used to change the feedback resistor divider ratio, through an open-drain output DRN pin. Bring CTRL high will connect DRN to ground through a low resistance (<100 Ω) switch; Bring CTRL low will put DRN pin to open circuit. User can simply connect a third resistor between feedback pin and DRN pin, to get a higher output level for

forced PWM mode and a lower level for asynchronous mode. MP2113 is designed to optimally ramp up and down the output voltage when CTRL changes state. Typically it takes about 10µs to ramp up the voltage and 30µs to ramp down the voltage.

PGOOD Indicator

MP2113 provides an open-drain PGOOD output that goes high after output level reaches regulation during startup. During mode switching where the output voltage level could be changed, there is a 200us de-glitch time on PGOOD to allow the output to settle to the desired level, and to avoid false trigger. PGOOD goes low if the output goes out of regulation by $\pm 10\%$ and the de-glitch times out, or when device enters shutdown.

APPLICATION INFORMATION

Output Voltage Setting

The external resistor divider sets the output voltage. The resistor R1 also sets the feedback loop bandwidth for the step-down converter. (see Figure 1).

Choose R1 to be between $200k-300k\Omega$ for optimal transient response. R2 is calculated using the desired output voltage for asynchronous mode:

$$R2 = \frac{R1}{\frac{V_{OUT_ASYNC}}{0.6V} - 1}$$

R3 is then calculated using R1, R2 and the desired output voltage for forced PWM mode:

$$R3 = \frac{R1 \| R2}{\frac{V_{OUT_FPWM}}{0.6V} \cdot \frac{R2}{R1 + R2} - 1}$$

If one want to have the same output voltage level for both operation mode, R3 will not be needed.

Table 1—Resistor Selection vs. Output Voltage Setting

V _{O_ASYNC} /V _{O_FPWM}	R1	R2	R3
0.9V/1.8V	301kΩ	604kΩ	200kΩ
	(1%)	(1%)	(1%)
1.2V/1.8V	301kΩ	301kΩ	301kΩ
	(1%)	(1%)	(1%)
1.2V/2.5V	301kΩ	301kΩ	137kΩ
	(1%)	(1%)	(1%)
1.5V/3.3V	301kΩ	200kΩ	100kΩ
	(1%)	(1%)	(1%)

Inductor Selection

A 1µH to 10µH inductor with DC current rating at least 25% higher than the maximum load current is recommended for most applications. For best efficiency, the inductor DC resistance shall be <200m Ω . For most designs, the inductance value can be derived from the following equation:

$$L = \frac{V_{OUT} \times (V_{IN} - V_{OUT})}{V_{IN} \times \Delta I_L \times f_{OSC}}$$

Where ΔI_{L} is inductor ripple current. Choose inductor ripple current approximately 30% of the maximum load current, 1.5A.

The maximum inductor peak current is:

 $I_{L(MAX)} = I_{LOAD} + \frac{\Delta I_{L}}{2}$

Manufacturer	Part Number	Inductance (µH)	Dimensions LxWxH (mm ³)
Wruth	7447745022	2.2	5.8X5.2X2
Toko	636CY- 2R2M	2.2	6.8X6X3.5
TDK	VLCF5020T- 2R2N2R6-1	2.2	5X5X2

Input Capacitor C_{IN} Selection

The input capacitor reduces the surge current drawn from the input and switching noise from the device. Ceramic capacitors with X5R or X7R dielectrics are highly recommended because of their low ESR and small temperature coefficients. For most applications, a 4.7μ F capacitor is sufficient.

Output Capacitor Cour Selection

The output capacitor keeps output voltage ripple small and ensures regulation loop stable. The output capacitor impedance shall be low at the switching frequency. Ceramic capacitors with X5R or X7R dielectrics are recommended. For forced PWM mode operation, the output ripple ΔV_{OUT} is approximately:

$$\Delta V_{OUT} = \frac{V_{OUT} \cdot (V_{IN} - V_{OUT})}{V_{IN} \cdot f_{OSC} \cdot L} (R_{ESR} + \frac{1}{8} \cdot \frac{1}{f_{OSC} \cdot C_{OUT}})$$

For asynchronous mode operation, the output ripple is the scaled amplitude of the feedback threshold hysteresis window:

$$\Delta V_{OUT} = (0.606V - 0.594V) \cdot \frac{R1 + R2}{R2}$$

Thermal Dissipation

Power dissipation shall be considered when MP2113 operates at maximum 1.5A output current. If the junction temperature rises above 150°C, MP2113 will be shut down by internal thermal protection circuitry.

The junction-to-ambient thermal resistance of the 8-pin QFN (2mm x 3mm) R_{OJA} is 50°C/W. The maximum allowable power dissipation is

about 1.6W when MP2113 is operating in a 70°C ambient temperature environment:

$$PD_{MAX} = \frac{150^{\circ}C - 70^{\circ}C}{50^{\circ}C/W} = 1.6W$$

PCB Layout

The high current paths (GND, IN and SW) should be placed very close to the device with short, direct and wide traces. Input capacitors should be placed as close as possible to the respective IN and GND pins. The external feedback resistors shall be placed next to the FB pins. Keep the switching nodes SW short and away from the feedback network.
