

NCV4290

Voltage Regulator - Low-Dropout, Power Good

5.0 V, 450 mA

The NCV4290 is an integrated low dropout regulator designed for use in harsh automotive environments. It includes wide operating temperature and input voltage ranges. The output is regulated at 5.0 V and is rated to 450 mA of output current. It also provides a number of features, including overcurrent protection, overtemperature protection and a programmable microprocessor power good signal. The NCV4290 is available in the DPAK and D²PAK surface mount packages. The output is stable over a wide output capacitance and ESR range.

Features

- 5.0 V, $\pm 2\%$ Output Voltage Options
- 450 mA Output Current
- Very Low Current Consumption
- Active Power Good Output
- Power Good Low Down to $V_Q = 1.0$ V
- 500 mV (max) Dropout Voltage
- Fault Protection
 - ♦ +45 V Peak Transient Voltage
 - ♦ -42 V Reverse Voltage
 - ♦ Short Circuit Protection
 - ♦ Thermal Overload Protection
- AEC-Q100 Qualified
- These are Pb-Free Devices

Applications

- Auto Body Electronics

NCV4290

PIN FUNCTION DESCRIPTION

Pin #	Symbol	Description
1	I	Input; Battery Supply Input Voltage. Bypass to ground with a ceramic capacitor.
2	PG	Power Good Output; Open Collector Active Power Good (accurate when $V_Q > 1.0$ V).
3, Tab	GND	Ground; Pin 3 internally connected to tab.
4	D	Power Good Delay; timing capacitor to GND for Power Good Delay function.
5	Q	Output; $\pm 2.0\%$, 450 mA output. Bypass with 22 μ F capacitor, ESR < 4.0 Ω .

MAXIMUM RATINGS

Rating	Symbol	Min	Max	Unit
Input Voltage	V_I	-42	45	V

APPLICATION INFORMATION

Figure 13. Test Circuit

Circuit Description

The NCV4290 is an integrated low dropout regulator that provides 5.0 V, 450 mA protected output and a signal for power on power good. The regulation is provided by a PNP pass transistor controlled by an error amplifier with a bandgap reference, which gives it the lowest possible drop out voltage and best possible temperature stability. The output current capability is 450 mA, and the base drive quiescent current is controlled to prevent over saturation when the input voltage is low or when the output is overloaded. The regulator is protected by both current limit and thermal shutdown. Thermal shutdown occurs above 150°C to protect the IC during overloads and extreme ambient temperatures. The delay time for the power good output is adjustable by selection of the timing capacitor. See Figure 13, Test Circuit, for circuit element nomenclature illustration.

Regulator

The error amplifier compares the reference voltage to a sample of the output voltage (V_Q) and drives the base of a PNP series pass transistor by a buffer. The reference is a bandgap design to give it a temperature-stable output. Saturation control of the PNP is a function of the load current and input voltage. Over saturation of the output power device is prevented, and quiescent current in the ground pin is minimized.

Regulator Stability Considerations

The input capacitors (C_{I1} and C_{I2}) are necessary to stabilize the input impedance to avoid voltage line influences. Using a resistor of approximately 1.0 Ω in series with C_{I2} can stop potential oscillations caused by stray inductance and capacitance.

The output capacitor helps determine three main characteristics of a linear regulator: startup delay, load transient response and loop stability. The capacitor value and type should be based on cost, availability, size and temperature constraints. A tantalum, aluminum or ceramic capacitors can be used. The range of stability versus capacitance, load current and capacitive ESR is illustrated in Figures 2 and 3. Minimum ESR for $C_Q = 22 \mu\text{F}$ is native ESR of ceramic capacitors. The aluminum electrolytic

capacitor is the least expensive solution, but, if the circuit operates at low temperatures (-25°C to -40°C), both the capacitance and ESR of the capacitor will vary considerably. The capacitor manufacturer's data sheet usually provides this information.

The value for the output capacitor C_Q shown in Figure 13, Test Circuit, should work for most applications; however, it is not necessarily the optimized solution. Stability is guaranteed for $C_Q \geq 22 \mu\text{F}$ and an $\text{ESR} \leq 4.0 \Omega$.

ESR characteristics were measured with ceramic capacitors and additional resistors to emulate ESR. Murata ceramic capacitors were used, GRM32ER71C226ME18 (22 μF , 16 V, X7R, 1210), GRM219R71E105KA88 (1 μF , 25 V, X7R, 0805).

Power Good Output

The power good output is used as the power on indicator to the microcontroller. This signal indicates when the output voltage is suitable for reliable operation of the controller. It pulls low when the output is not considered to be ready. PG is pulled up to V_Q by an external resistor, typically 5.0 k Ω in value. Hysteresis is implemented for PG signal. When output voltage is decreasing PG goes Low at V_Q typ 3.65 V and when output voltage is increasing PG goes High at V_Q typ 4.65 V. The input and output conditions that control the Power Good Output and the relative timing are illustrated in Figure 14, Power Good Timing.

Output voltage regulation must be maintained for the delay time before the power good output signals a valid condition. The delay for the power good output is defined as the amount of time it takes the timing capacitor on the delay pin to charge from a residual voltage of 0.0 V to the upper timing threshold voltage V_{DU} . The charging current for this is $I_{D,C}$ and D pin voltage in steady state is typically 2.85 V. By using typical IC parameters with a 47 nF capacitor on the D pin, the following time delay for 5.0 V regulator is derived:

$$t_{RD} = C_D V_{DU} / I_{D,C}$$

$$t_{RD} = 47 \text{ nF} (1.8 \text{ V}) / 6.0 \mu\text{A} = 14.1 \text{ ms}$$

Other time delays can be obtained by changing the capacitor value.

The diagram illustrates the behavior of the Power Good (PG) signal under various fault conditions. The signals shown are V_I (Input Voltage), V_Q (Output Voltage), V_D (Driver Voltage), and V_{PG} (Power Good Signal). The conditions and their corresponding PG signal behavior are:

- Power-on:** V_I rises above the upper timing threshold V_{DU} . V_{PG} transitions from low to high after a delay t_{rd} (PG Delay Time).
- Power Good:** V_I is stable above V_{DU} . V_{PG} is high.
- Thermal Shutdown:** V_I drops below the lower timing threshold V_{DL} . V_{PG} transitions from high to low after a delay t_{rr} (PG Reaction Time).
- Voltage Dip at Input Not Lower than 4 V:** V_I dips but remains above V_{DL} . V_{PG} remains high.
- Undervoltage:** V_I drops below V_{DL} . V_{PG} transitions from high to low.
- Secondary Spike:** V_I has a narrow spike above V_{DU} . V_{PG} remains low.
- Overload at Output:** V_Q drops, causing V_D to rise above V_{DU} . V_{PG} transitions from low to high.

Key parameters and thresholds shown in the diagram include:

- V_{Q,pgt_i} and V_{Q,pgt_d} : Output voltage thresholds for PG transition.
- t_{rd} : PG Delay Time.
- t_{rr} : PG Reaction Time.
- $< t_{rr}$ (PG Reaction Time): Time interval for a spike.
- $\frac{dV}{dt} = \frac{I_{D,C}}{C_D}$: Rate of change of driver voltage.
- Upper Timing Threshold V_{DU} .
- Lower Timing Threshold V_{DL} .

Calculating Power Dissipation in a Single Output Linear Regulator

The maximum power dissipation for a single output regulator (Figure 15) is:

$$P_{D(max)} = [V_{I(max)} - V_{Q(min)}] I_{Q(max)} + V_{I(max)} I_q \quad (1)$$

where

$V_{I(max)}$ is the maximum input voltage,

$V_{Q(min)}$ is the minimum output voltage,

$I_{Q(max)}$ is the maximum output current for the application,

I_q is the quiescent current the regulator consumes at $I_{Q(max)}$.

Once the value of $P_{D(max)}$ is known, the maximum permissible value of $R_{\theta JA}$ can be calculated:

$$R_{\theta JA} = \frac{150^\circ\text{C} - T_A}{P_D} \quad (2)$$

The value of $R_{\theta JA}$ can then be compared with those in the package section of the data sheet. Those packages with $R_{\theta JA}$'s less than the calculated value in Equation 2 will keep the die temperature below 150°C .

In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required.

Figure 15. Single Output Regulator with Key Performance Parameters Labeled

Heatsinks

A heatsink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $R_{\theta JA}$:

$$R_{\theta JA} = R_{\theta JC} + R_{\theta CS} + R_{\theta SA} \quad (3)$$

where

$R_{\theta JC}$ is the junction-to-case thermal resistance,

$R_{\theta CS}$ is the case-to-heatsink thermal resistance,

$R_{\theta SA}$ is the heatsink-to-ambient thermal resistance.

$R_{\theta JC}$ appears in the package section of the data sheet. Like $R_{\theta JA}$, it too is a function of package type. $R_{\theta CS}$ and $R_{\theta SA}$ are functions of the package type, heatsink and the interface between them. These values appear in heatsink data sheets of heatsink manufacturers.

Thermal, mounting, and heatsinking considerations are discussed in the ON Semiconductor application note AN1040/D.

Thermal Model

A discussion of thermal modeling is in the ON Semiconductor web site: <http://www.onsemi.com/pub/collateral/BR1487-D.PDF>.

NOTE: Bold face items represent the package without the external thermal system.

The Cauer networks generally have physical significance and may be divided between nodes to separate thermal behavior due to one portion of the network from another. The Foster networks, though when sorted by time constant (as above) bear a rough correlation with the Cauer networks, are really only convenient mathematical models. Cauer networks can be easily implemented using circuit simulating tools, whereas Foster networks may be more easily implemented using mathematical tools (for instance, in a spreadsheet program), according to the following formula:

$$R(t) = \sum_{i=1}^n R_i (1 - e^{-t/\tau_{ui}})$$

RECOMMENDED SOLDERING FOOTPRINT*

*For additional information on our Pb-Free strategy and soldering details, please download the ON Semiconductor Soldering and Mounting Techniques Reference Manual, SOLDERRM/D.

GENERIC MARKING DIAGRAMS*

XXXXXX = Device Code
 A = Assembly Location
 L = Wafer Lot
 Y = Year
 WW = Work Week
 G = Pb-Free Package

*This information is generic. Please refer to device data sheet for actual part marking. Pb-Free indicator, "G" or microdot "▪", may or may not be present.

DOCUMENT NUMBER:	98AON12855D	Electronic versions are uncontrolled except when accessed directly from the Document Repository. Printed versions are uncontrolled except when stamped "CONTROLLED COPY" in red.
DESCRIPTION:	DPAK-5 CENTER LEAD CROP	PAGE 1 OF 1

MECHANICAL CASE OUTLINE

PACKAGE DIMENSIONS

ON Semiconductor®

ON

D²PAK 5-LEAD CASE 936A-02 ISSUE E

DATE 28 JUL 2021

SCALE 1:1

NOTES:

1. DIMENSIONING AND TOLERANCING PER ANSI Y14.5M, 1982.
2. CONTROLLING DIMENSION: INCHES
3. TAB CONTOUR OPTIONAL WITHIN DIMENSIONS A AND K.
4. DIMENSIONS U AND V ESTABLISH A MINIMUM MOUNTING SURFACE FOR TERMINAL 4.
5. DIMENSIONS A AND B DO NOT INCLUDE MOLD FLASH OR GATE PROTRUSIONS. MOLD FLASH AND GATE PROTRUSIONS NOT TO EXCEED 0.025 (0.635) MAXIMUM.

GENERIC MARKING DIAGRAM*

xxxxxx = Device Code
A = Assembly Location
WL = Wafer Lot
Y = Year
WW = Work Week
G = Pb-Free Package

*This information is generic. Please refer to device data sheet for actual part marking. Pb-Free indicator, "G" or microdot "•", may or may not be present. Some products may not follow the Generic Marking.

* For additional information on our Pb-Free strategy and soldering details, please download the ON Semiconductor Soldering and Mounting Techniques Reference Manual, SOLDERRM/D.
